- path: 02_lb_ext.py
- path: 02_lb_int.py 1
resources:
- name: cluster-lb-ext 2
  type: 02_lb_ext.py
  properties:
    infra_id: '${INFRA_ID}' 3
    region: '${REGION}' 4
- name: cluster-lb-int
  type: 02_lb_int.py
  properties:
    cluster_network: '${CLUSTER_NETWORK}'
    control_subnet: '${CONTROL_SUBNET}' 5
    infra_id: '${INFRA_ID}'
```

```

region: '${REGION}'
zones: ⑥
- '${ZONE_0}'
- '${ZONE_1}'
- '${ZONE_2}'
EOF

```

① ② Required only when deploying an external cluster.

③ **infra_id** is the **INFRA_ID** infrastructure name from the extraction step.

④ **region** is the region to deploy the cluster into, for example **us-central1**.

⑤ **control_subnet** is the URI to the control subnet.

⑥ **zones** are the zones to deploy the control plane instances into, like **us-east1-b, us-east1-c, and us-east1-d**.

5. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-infra --config 02_infra.yaml
```

6. Export the cluster IP address:

```
$ export CLUSTER_IP=`gcloud compute addresses describe ${INFRA_ID}-cluster-ip --region=${REGION} --format json | jq -r .address`
```

7. For an external cluster, also export the cluster public IP address:

```
$ export CLUSTER_PUBLIC_IP=`gcloud compute addresses describe ${INFRA_ID}-cluster-public-ip --region=${REGION} --format json | jq -r .address`
```

7.11.9.1. Deployment Manager template for the external load balancer

You can use the following Deployment Manager template to deploy the external load balancer that you need for your OpenShift Container Platform cluster:

Example 7.11. 02_lb_ext.py Deployment Manager template

```

def GenerateConfig(context):

resources = [
    'name': context.properties['infra_id'] + '-cluster-public-ip',
    'type': 'compute.v1.address',
    'properties': {
        'region': context.properties['region']
    }
], {
    # Refer to docs/dev/kube-apiserver-health-check.md on how to correctly setup health check
    # probe for kube-apiserver
    'name': context.properties['infra_id'] + '-api-http-health-check',
    'type': 'compute.v1.httpHealthCheck',
    'properties': {

```

```

        'port': 6080,
        'requestPath': '/readyz'
    },
    {
        'name': context.properties['infra_id'] + '-api-target-pool',
        'type': 'compute.v1.targetPool',
        'properties': {
            'region': context.properties['region'],
            'healthChecks': ['$(ref.' + context.properties['infra_id'] + '-api-http-health-check.selfLink)'],
            'instances': []
        }
    },
    {
        'name': context.properties['infra_id'] + '-api-forwarding-rule',
        'type': 'compute.v1.forwardingRule',
        'properties': {
            'region': context.properties['region'],
            'IPAddress': '$(ref.' + context.properties['infra_id'] + '-cluster-public-ip.selfLink)',
            'target': '$(ref.' + context.properties['infra_id'] + '-api-target-pool.selfLink)',
            'portRange': '6443'
        }
    }
]

return {'resources': resources}

```

7.11.9.2. Deployment Manager template for the internal load balancer

You can use the following Deployment Manager template to deploy the internal load balancer that you need for your OpenShift Container Platform cluster:

Example 7.12. 02_lb_int.py Deployment Manager template

```

def GenerateConfig(context):

    backends = []
    for zone in context.properties['zones']:
        backends.append({
            'group': '$(ref.' + context.properties['infra_id'] + '-master-' + zone + '-instance-group' +
            '.selfLink)'
        })

    resources = [
        {
            'name': context.properties['infra_id'] + '-cluster-ip',
            'type': 'compute.v1.address',
            'properties': {
                'addressType': 'INTERNAL',
                'region': context.properties['region'],
                'subnetwork': context.properties['control_subnet']
            }
        },
        {
            # Refer to docs/dev/kube-apiserver-health-check.md on how to correctly setup health check
            # probe for kube-apiserver
            'name': context.properties['infra_id'] + '-api-internal-health-check',
            'type': 'compute.v1.healthCheck',
            'properties': {

```

```

'httpsHealthCheck': {
    'port': 6443,
    'requestPath': '/readyz'
},
'type': "HTTPS"
}
}, {
    'name': context.properties['infra_id'] + '-api-internal-backend-service',
    'type': 'compute.v1.regionBackendService',
    'properties': {
        'backends': backends,
        'healthChecks': ['$ref.' + context.properties['infra_id'] + '-api-internal-health-
check.selfLink'],
        'loadBalancingScheme': 'INTERNAL',
        'region': context.properties['region'],
        'protocol': 'TCP',
        'timeoutSec': 120
    }
},
{
    'name': context.properties['infra_id'] + '-api-internal-forwarding-rule',
    'type': 'compute.v1.forwardingRule',
    'properties': {
        'backendService': '$(ref.' + context.properties['infra_id'] + '-api-internal-backend-
service.selfLink)',
        'IPAddress': '$(ref.' + context.properties['infra_id'] + '-cluster-ip.selfLink)',
        'loadBalancingScheme': 'INTERNAL',
        'ports': ['6443','22623'],
        'region': context.properties['region'],
        'subnetwork': context.properties['control_subnet']
    }
}
]

for zone in context.properties['zones']:
    resources.append({
        'name': context.properties['infra_id'] + '-master-' + zone + '-instance-group',
        'type': 'compute.v1.instanceGroup',
        'properties': {
            'namedPorts': [
                {
                    'name': 'ignition',
                    'port': 22623
                },
                {
                    'name': 'https',
                    'port': 6443
                }
            ],
            'network': context.properties['cluster_network'],
            'zone': zone
        }
    })
}

return {'resources': resources}

```

You will need this template in addition to the **02_lb_ext.py** template when you create an external cluster.

7.11.10. Creating a private DNS zone in GCP

You must configure a private DNS zone in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create this component is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure

1. Copy the template from the **Deployment Manager template for the private DNS** section of this topic and save it as **02_dns.py** on your computer. This template describes the private DNS objects that your cluster requires.
2. Create a **02_dns.yaml** resource definition file:

```
$ cat <<EOF >02_dns.yaml
imports:
- path: 02_dns.py

resources:
- name: cluster-dns
  type: 02_dns.py
  properties:
    infra_id: '${INFRA_ID}' 1
    cluster_domain: '${CLUSTER_NAME}.${BASE_DOMAIN}' 2
    cluster_network: '${CLUSTER_NETWORK}' 3
EOF
```

- 1** **infra_id** is the **INFRA_ID** infrastructure name from the extraction step.
- 2** **cluster_domain** is the domain for the cluster, for example **openshift.example.com**.
- 3** **cluster_network** is the **selfLink** URL to the cluster network.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-dns --config 02_dns.yaml --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
```

4. The templates do not create DNS entries due to limitations of Deployment Manager, so you must create them manually:

- a. Add the internal DNS entries:

```
$ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api-int.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
```

- b. For an external cluster, also add the external DNS entries:

```
$ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} dns record-sets transaction add ${CLUSTER_PUBLIC_IP} --name api.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone ${BASE_DOMAIN_ZONE_NAME}
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} dns record-sets transaction execute --zone ${BASE_DOMAIN_ZONE_NAME}
```

7.11.10.1. Deployment Manager template for the private DNS

You can use the following Deployment Manager template to deploy the private DNS that you need for your OpenShift Container Platform cluster:

Example 7.13. 02_dns.py Deployment Manager template

```
def GenerateConfig(context):
    resources = [
        {
            'name': context.properties['infra_id'] + '-private-zone',
            'type': 'dns.v1.managedZone',
            'properties': {
                'description': '',
                'dnsName': context.properties['cluster_domain'] + '',
                'visibility': 'private',
                'privateVisibilityConfig': {
                    'networks': [
                        {
                            'networkUrl': context.properties['cluster_network']
                        }
                    ]
                }
            }
        }
    ]
    return {'resources': resources}
```

7.11.11. Creating firewall rules in GCP

You must create firewall rules in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure

1. Copy the template from the **Deployment Manager template for firewall rules** section of this topic and save it as **03_firewall.py** on your computer. This template describes the security groups that your cluster requires.
2. Create a **03_firewall.yaml** resource definition file:

```
$ cat <<EOF >03_firewall.yaml
imports:
- path: 03_firewall.py

resources:
- name: cluster-firewall
  type: 03_firewall.py
properties:
  allowed_external_cidr: '0.0.0.0/0' 1
  infra_id: '${INFRA_ID}' 2
  cluster_network: '${CLUSTER_NETWORK}' 3
  network_cidr: '${NETWORK_CIDR}' 4
EOF
```

- 1** **allowed_external_cidr** is the CIDR range that can access the cluster API and SSH to the bootstrap host. For an internal cluster, set this value to **\${NETWORK_CIDR}**.
- 2** **infra_id** is the **INFRA_ID** infrastructure name from the extraction step.
- 3** **cluster_network** is the **selfLink** URL to the cluster network.
- 4** **network_cidr** is the CIDR of the VPC network, for example **10.0.0.0/16**.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-firewall --config
03_firewall.yaml --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
```

7.11.11.1. Deployment Manager template for firewall rules

You can use the following Deployment Manager template to deploy the firewall rules that you need for your OpenShift Container Platform cluster:

Example 7.14. 03_firewall.py Deployment Manager template

```
def GenerateConfig(context):

    resources = [
        {
            'name': context.properties['infra_id'] + '-bootstrap-in-ssh',
            'type': 'compute.v1.firewall',
            'properties': {
                'network': context.properties['cluster_network'],
                'allowed': [
                    {
                        'IPProtocol': 'tcp',
                        'ports': ['22']
                    }
                ],
                'sourceRanges': [context.properties['allowed_external_cidr']],
                'targetTags': [context.properties['infra_id'] + '-bootstrap']
            }
        },
        {
            'name': context.properties['infra_id'] + '-api',
            'type': 'compute.v1.firewall',
            'properties': {
                'network': context.properties['cluster_network'],
                'allowed': [
                    {
                        'IPProtocol': 'tcp',
                        'ports': ['6443']
                    }
                ],
                'sourceRanges': [context.properties['allowed_external_cidr']],
                'targetTags': [context.properties['infra_id'] + '-master']
            }
        },
        {
            'name': context.properties['infra_id'] + '-health-checks',
            'type': 'compute.v1.firewall',
            'properties': {
                'network': context.properties['cluster_network'],
                'allowed': [
                    {
                        'IPProtocol': 'tcp',
                        'ports': ['6080', '6443', '22624']
                    }
                ],
                'sourceRanges': ['35.191.0.0/16', '130.211.0.0/22', '209.85.152.0/22', '209.85.204.0/22'],
                'targetTags': [context.properties['infra_id'] + '-master']
            }
        },
        {
            'name': context.properties['infra_id'] + '-etcd',
            'type': 'compute.v1.firewall',
            'properties': {
                'network': context.properties['cluster_network'],
                'allowed': [
                    {
                        'IPProtocol': 'tcp',
                    }
                ]
            }
        }
    ]
```

```
        'ports': [2379-2380]
    }],
    'sourceTags': [context.properties['infra_id'] + '-master'],
    'targetTags': [context.properties['infra_id'] + '-master']
}
}, {
    'name': context.properties['infra_id'] + '-control-plane',
    'type': 'compute.v1.firewall',
    'properties': {
        'network': context.properties['cluster_network'],
        'allowed': [{
            'IPProtocol': 'tcp',
            'ports': [10257]
        },{
            'IPProtocol': 'tcp',
            'ports': [10259]
        },{
            'IPProtocol': 'tcp',
            'ports': [22623]
        }],
        'sourceTags': [
            context.properties['infra_id'] + '-master',
            context.properties['infra_id'] + '-worker'
        ],
        'targetTags': [context.properties['infra_id'] + '-master']
    }
}, {
    'name': context.properties['infra_id'] + '-internal-network',
    'type': 'compute.v1.firewall',
    'properties': {
        'network': context.properties['cluster_network'],
        'allowed': [{
            'IPProtocol': 'icmp'
        },{
            'IPProtocol': 'tcp',
            'ports': [22]
        }],
        'sourceRanges': [context.properties['network_cidr']],
        'targetTags': [
            context.properties['infra_id'] + '-master',
            context.properties['infra_id'] + '-worker'
        ]
    }
}, {
    'name': context.properties['infra_id'] + '-internal-cluster',
    'type': 'compute.v1.firewall',
    'properties': {
        'network': context.properties['cluster_network'],
        'allowed': [{
            'IPProtocol': 'udp',
            'ports': [4789, 6081]
        },{
            'IPProtocol': 'udp',
            'ports': [500, 4500]
        },{
            'IPProtocol': 'esp',
            'ports': [500, 4500]
        }]
    }
}
```

```

        },{
          'IPProtocol': 'tcp',
          'ports': ['9000-9999']
        },{
          'IPProtocol': 'udp',
          'ports': ['9000-9999']
        },{
          'IPProtocol': 'tcp',
          'ports': ['10250']
        },{
          'IPProtocol': 'tcp',
          'ports': ['30000-32767']
        },{
          'IPProtocol': 'udp',
          'ports': ['30000-32767']
        },
      ],
      'sourceTags': [
        context.properties['infra_id'] + '-master',
        context.properties['infra_id'] + '-worker'
      ],
      'targetTags': [
        context.properties['infra_id'] + '-master',
        context.properties['infra_id'] + '-worker'
      ]
    }
  ]
}

return {'resources': resources}

```

7.11.12. Creating IAM roles in GCP

You must create IAM roles in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure

1. Copy the template from the **Deployment Manager template for IAM roles** section of this topic and save it as **03_iam.py** on your computer. This template describes the IAM roles that your cluster requires.
2. Create a **03_iam.yaml** resource definition file:

```
$ cat <<EOF >03_iam.yaml
imports:
- path: 03_iam.py
resources:
- name: cluster-iam
  type: 03_iam.py
  properties:
    infra_id: '${INFRA_ID}' 1
EOF
```

1 **infra_id** is the **INFRA_ID** infrastructure name from the extraction step.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-iam --config 03_iam.yaml
```

4. Export the variable for the master service account:

```
$ export MASTER_SERVICE_ACCOUNT=`gcloud iam service-accounts list --filter "email~^${INFRA_ID}-m@${PROJECT_NAME}." --format json | jq -r '[0].email'`
```

5. Export the variable for the worker service account:

```
$ export WORKER_SERVICE_ACCOUNT=`gcloud iam service-accounts list --filter "email~^${INFRA_ID}-w@${PROJECT_NAME}." --format json | jq -r '[0].email'`
```

6. Assign the permissions that the installation program requires to the service accounts for the subnets that host the control plane and compute subnets:

- a. Grant the **networkViewer** role of the project that hosts your shared VPC to the master service account:

```
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} projects add-iam-policy-binding ${HOST_PROJECT} --member "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkViewer"
```

- b. Grant the **networkUser** role to the master service account for the control plane subnet:

```
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} compute networks subnets add-iam-policy-binding "${HOST_PROJECT_CONTROL_SUBNET}" --member "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkUser" --region ${REGION}
```

- c. Grant the **networkUser** role to the worker service account for the control plane subnet:

```
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
compute networks subnets add-iam-policy-binding
"${HOST_PROJECT_CONTROL_SUBNET}" --member
"serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role
"roles/compute.networkUser" --region ${REGION}
```

- d. Grant the **networkUser** role to the master service account for the compute subnet:

```
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
compute networks subnets add-iam-policy-binding
"${HOST_PROJECT_COMPUTE_SUBNET}" --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkUser"
--region ${REGION}
```

- e. Grant the **networkUser** role to the worker service account for the compute subnet:

```
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
compute networks subnets add-iam-policy-binding
"${HOST_PROJECT_COMPUTE_SUBNET}" --member
"serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role
"roles/compute.networkUser" --region ${REGION}
```

7. The templates do not create the policy bindings due to limitations of Deployment Manager, so you must create them manually:

```
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.instanceAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.securityAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/iam.serviceAccountUser"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/storage.admin"

$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role "roles/compute.viewer"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role "roles/storage.admin"
```

8. Create a service account key and store it locally for later use:

```
$ gcloud iam service-accounts keys create service-account-key.json --iam-
account=${MASTER_SERVICE_ACCOUNT}
```

7.11.12.1. Deployment Manager template for IAM roles

You can use the following Deployment Manager template to deploy the IAM roles that you need for your OpenShift Container Platform cluster:

Example 7.15. 03_iam.py Deployment Manager template

```
def GenerateConfig(context):

    resources = [
        {
            'name': context.properties['infra_id'] + '-master-node-sa',
            'type': 'iam.v1.serviceAccount',
            'properties': {
                'accountId': context.properties['infra_id'] + '-m',
                'displayName': context.properties['infra_id'] + '-master-node'
            }
        },
        {
            'name': context.properties['infra_id'] + '-worker-node-sa',
            'type': 'iam.v1.serviceAccount',
            'properties': {
                'accountId': context.properties['infra_id'] + '-w',
                'displayName': context.properties['infra_id'] + '-worker-node'
            }
        }
    ]

    return {'resources': resources}
```

7.11.13. Creating the RHCOS cluster image for the GCP infrastructure

You must use a valid Red Hat Enterprise Linux CoreOS (RHCOS) image for Google Cloud Platform (GCP) for your OpenShift Container Platform nodes.

Procedure

1. Obtain the RHCOS image from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

The file name contains the OpenShift Container Platform version number in the format **rhcoss-<version>-<arch>-gcp.<arch>.tar.gz**.

2. Create the Google storage bucket:

```
$ gsutil mb gs://<bucket_name>
```

3. Upload the RHCOS image to the Google storage bucket:

```
$ gsutil cp <downloaded_image_file_path>/rhcoss-<version>-x86_64-gcp.x86_64.tar.gz
gs://<bucket_name>
```

4. Export the uploaded RHCOS image location as a variable:

```
$ export IMAGE_SOURCE='gs://<bucket_name>/rhcos-<version>-x86_64-gcp.x86_64.tar.gz'
```

5. Create the cluster image:

```
$ gcloud compute images create "${INFRA_ID}-rhcos-image" \
--source-uri="${IMAGE_SOURCE}"
```

7.11.14. Creating the bootstrap machine in GCP

You must create the bootstrap machine in Google Cloud Platform (GCP) to use during OpenShift Container Platform cluster initialization. One way to create this machine is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your bootstrap machine, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Ensure pyOpenSSL is installed.

Procedure

1. Copy the template from the **Deployment Manager template for the bootstrap machine** section of this topic and save it as **04_bootstrap.py** on your computer. This template describes the bootstrap machine that your cluster requires.
2. Export the location of the Red Hat Enterprise Linux CoreOS (RHCOS) image that the installation program requires:

```
$ export CLUSTER_IMAGE=(`gcloud compute images describe ${INFRA_ID}-rhcos-image --format json | jq -r .selfLink`)
```

3. Create a bucket and upload the **bootstrap.ign** file:

```
$ gsutil mb gs://${INFRA_ID}-bootstrap-ignition
$ gsutil cp <installation_directory>/bootstrap.ign gs://${INFRA_ID}-bootstrap-ignition/
```

4. Create a signed URL for the bootstrap instance to use to access the Ignition config. Export the URL from the output as a variable:

```
$ export BOOTSTRAP_IGN=$(gsutil signurl -d 1h service-account-key.json gs://${INFRA_ID}-bootstrap-ignition/bootstrap.ign | grep '^gs:' | awk '{print $5}'")
```

5. Create a **04_bootstrap.yaml** resource definition file:

```
$ cat <<EOF >04_bootstrap.yaml
imports:
- path: 04_bootstrap.py

resources:
- name: cluster-bootstrap
  type: 04_bootstrap.py
  properties:
    infra_id: '${INFRA_ID}' 1
    region: '${REGION}' 2
    zone: '${ZONE_0}' 3

    cluster_network: '${CLUSTER_NETWORK}' 4
    control_subnet: '${CONTROL_SUBNET}' 5
    image: '${CLUSTER_IMAGE}' 6
    machine_type: 'n1-standard-4' 7
    root_volume_size: '128' 8

    bootstrap_ign: '${BOOTSTRAP_IGN}' 9
EOF
```

- 1** **infra_id** is the **INFRA_ID** infrastructure name from the extraction step.
- 2** **region** is the region to deploy the cluster into, for example **us-central1**.
- 3** **zone** is the zone to deploy the bootstrap instance into, for example **us-central1-b**.
- 4** **cluster_network** is the **selfLink** URL to the cluster network.
- 5** **control_subnet** is the **selfLink** URL to the control subnet.
- 6** **image** is the **selfLink** URL to the RHCOS image.
- 7** **machine_type** is the machine type of the instance, for example **n1-standard-4**.
- 8** **root_volume_size** is the boot disk size for the bootstrap machine.
- 9** **bootstrap_ign** is the URL output when creating a signed URL.

6. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-bootstrap --config 04_bootstrap.yaml
```

7. Add the bootstrap instance to the internal load balancer instance group:

```
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-bootstrap-instance-group --zone=${ZONE_0} --instances=${INFRA_ID}-bootstrap
```

8. Add the bootstrap instance group to the internal load balancer backend service:

```
$ gcloud compute backend-services add-backend ${INFRA_ID}-api-internal-backend-service --region=${REGION} --instance-group=${INFRA_ID}-bootstrap-instance-group --instance-group-zone=${ZONE_0}
```

7.11.14.1. Deployment Manager template for the bootstrap machine

You can use the following Deployment Manager template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster:

Example 7.16. 04_bootstrap.py Deployment Manager template

```
def GenerateConfig(context):
    resources = [
        {
            'name': context.properties['infra_id'] + '-bootstrap-public-ip',
            'type': 'compute.v1.address',
            'properties': {
                'region': context.properties['region']
            }
        },
        {
            'name': context.properties['infra_id'] + '-bootstrap',
            'type': 'compute.v1.instance',
            'properties': {
                'disks': [
                    {
                        'autoDelete': True,
                        'boot': True,
                        'initializeParams': {
                            'diskSizeGb': context.properties['root_volume_size'],
                            'sourceImage': context.properties['image']
                        }
                    }
                ],
                'machineType': 'zones/' + context.properties['zone'] + '/machineTypes/' +
                context.properties['machine_type'],
                'metadata': {
                    'items': [
                        {
                            'key': 'user-data',
                            'value': '{"ignition":{"config":{"replace":{"source":"' + context.properties['bootstrap_ign'] +
                            '"}},"version":"3.1.0"}}'
                        }
                    ],
                    'networkInterfaces': [
                        {
                            'subnetwork': context.properties['control_subnet'],
                            'accessConfigs': [
                                {
                                    'natIP': '$(ref.' + context.properties['infra_id'] + '-bootstrap-public-ip.address)'
                                }
                            ]
                        },
                        {
                            'tags': {
                                'items': [
                                    context.properties['infra_id'] + '-master',
                                    context.properties['infra_id'] + '-bootstrap'
                                ]
                            }
                        }
                    ]
                }
            }
        }
    ]
    return {'resources': resources}
```

```

        ],
      },
      'zone': context.properties['zone']
    },
    {
      'name': context.properties['infra_id'] + '-bootstrap-instance-group',
      'type': 'compute.v1.instanceGroup',
      'properties': {
        'namedPorts': [
          {
            'name': 'ignition',
            'port': 22623
          },
          {
            'name': 'https',
            'port': 6443
          }
        ],
        'network': context.properties['cluster_network'],
        'zone': context.properties['zone']
      }
    }
  ],
  return {'resources': resources}

```

7.11.15. Creating the control plane machines in GCP

You must create the control plane machines in Google Cloud Platform (GCP) for your cluster to use. One way to create these machines is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.

Procedure

1. Copy the template from the **Deployment Manager template for control plane machines** section of this topic and save it as **05_control_plane.py** on your computer. This template describes the control plane machines that your cluster requires.
2. Export the following variable required by the resource definition:

```
$ export MASTER_IGNITION=`cat <installation_directory>/master.ign`
```

3. Create a **05_control_plane.yaml** resource definition file:

```
$ cat <<EOF >05_control_plane.yaml
imports:
- path: 05_control_plane.py

resources:
- name: cluster-control-plane
  type: 05_control_plane.py
  properties:
    infra_id: '${INFRA_ID}' 1
    zones: 2
    - '${ZONE_0}'
    - '${ZONE_1}'
    - '${ZONE_2}'

    control_subnet: '${CONTROL_SUBNET}' 3
    image: '${CLUSTER_IMAGE}' 4
    machine_type: 'n1-standard-4' 5
    root_volume_size: '128'
    service_account_email: '${MASTER_SERVICE_ACCOUNT}' 6

    ignition: '${MASTER_IGNITION}' 7
EOF
```

- 1** **infra_id** is the **INFRA_ID** infrastructure name from the extraction step.
- 2** **zones** are the zones to deploy the control plane instances into, for example **us-central1-a**, **us-central1-b**, and **us-central1-c**.
- 3** **control_subnet** is the **selfLink** URL to the control subnet.
- 4** **image** is the **selfLink** URL to the RHCOS image.
- 5** **machine_type** is the machine type of the instance, for example **n1-standard-4**.
- 6** **service_account_email** is the email address for the master service account that you created.
- 7** **ignition** is the contents of the **master.ign** file.

4. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-control-plane --config
05_control_plane.yaml
```

5. The templates do not manage load balancer membership due to limitations of Deployment Manager, so you must add the control plane machines manually.

- Run the following commands to add the control plane machines to the appropriate instance groups:

```
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-0
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-1
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-2
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-3
```

- For an external cluster, you must also run the following commands to add the control plane machines to the target pools:

```
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances=0
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances=1
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances=2
```

7.11.15.1. Deployment Manager template for control plane machines

You can use the following Deployment Manager template to deploy the control plane machines that you need for your OpenShift Container Platform cluster:

Example 7.17. 05_control_plane.py Deployment Manager template

```
def GenerateConfig(context):
    resources = [
        {
            'name': context.properties['infra_id'] + '-master-0',
            'type': 'compute.v1.instance',
            'properties': {
                'disks': [
                    {
                        'autoDelete': True,
                        'boot': True,
                        'initializeParams': {
                            'diskSizeGb': context.properties['root_volume_size'],
                            'diskType': 'zones/' + context.properties['zones'][0] + '/diskTypes/pd-ssd',
                            'sourceImage': context.properties['image']
                        }
                    }
                ],
                'machineType': 'zones/' + context.properties['zones'][0] + '/machineTypes/' +
                context.properties['machine_type'],
                'metadata': {
                    'items': [
                        {
                            'key': 'user-data',
                            'value': context.properties['ignition']
                        }
                    ]
                },
                'networkInterfaces': [
                    {
                        'subnetwork': context.properties['control_subnet']
                    }
                ]
            }
        }
    ]
```

```

}],
'serviceAccounts': [
  'email': context.properties['service_account_email'],
  'scopes': ['https://www.googleapis.com/auth/cloud-platform']
],
'tags': {
  'items': [
    context.properties['infra_id'] + '-master',
  ]
},
'zone': context.properties['zones'][0]
}
},
{
'name': context.properties['infra_id'] + '-master-1',
'type': 'compute.v1.instance',
'properties': {
  'disks': [
    {
      'autoDelete': True,
      'boot': True,
      'initializeParams': {
        'diskSizeGb': context.properties['root_volume_size'],
        'diskType': 'zones/' + context.properties['zones'][1] + '/diskTypes/pd-ssd',
        'sourceImage': context.properties['image']
      }
    },
    {
      'machineType': 'zones/' + context.properties['zones'][1] + '/machineTypes/' +
context.properties['machine_type'],
      'metadata': {
        'items': [
          {
            'key': 'user-data',
            'value': context.properties['ignition']
          }
        ],
        'networkInterfaces': [
          {
            'subnetwork': context.properties['control_subnet']
          }
        ],
        'serviceAccounts': [
          {
            'email': context.properties['service_account_email'],
            'scopes': ['https://www.googleapis.com/auth/cloud-platform']
          }
        ],
        'tags': {
          'items': [
            context.properties['infra_id'] + '-master',
          ]
        },
        'zone': context.properties['zones'][1]
      }
    },
    {
      'name': context.properties['infra_id'] + '-master-2',
      'type': 'compute.v1.instance',
      'properties': {
        'disks': [
          {
            'autoDelete': True,
            'boot': True,
            'initializeParams': {
              'diskSizeGb': context.properties['root_volume_size'],
            }
          }
        ]
      }
    }
  ]
}
}

```

```
        'diskType': 'zones/' + context.properties['zones'][2] + '/diskTypes/pd-ssd',
        'sourceImage': context.properties['image']
    }
},
'machineType': 'zones/' + context.properties['zones'][2] + '/machineTypes/' +
context.properties['machine_type'],
'metadata': {
    'items': [
        {
            'key': 'user-data',
            'value': context.properties['ignition']
        }
    ],
    'networkInterfaces': [
        {
            'subnetwork': context.properties['control_subnet']
        }
    ],
    'serviceAccounts': [
        {
            'email': context.properties['service_account_email'],
            'scopes': ['https://www.googleapis.com/auth/cloud-platform']
        }
    ],
    'tags': {
        'items': [
            context.properties['infra_id'] + '-master',
        ]
    },
    'zone': context.properties['zones'][2]
}
}

return {'resources': resources}
```

7.11.16. Wait for bootstrap completion and remove bootstrap resources in GCP

After you create all of the required infrastructure in Google Cloud Platform (GCP), wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

Procedure

1. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install wait-for bootstrap-complete --dir=<installation_directory> \ ①
--log-level info ②
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

If the command exits without a **FATAL** warning, your production control plane has initialized.

- 2 Delete the bootstrap resources:

```
$ gcloud compute backend-services remove-backend ${INFRA_ID}-api-internal-backend-service --region=${REGION} --instance-group=${INFRA_ID}-bootstrap-instance-group --instance-group-zone=${ZONE_0}
$ gsutil rm gs://${INFRA_ID}-bootstrap-ignition/bootstrap.ign
$ gsutil rb gs://${INFRA_ID}-bootstrap-ignition
$ gcloud deployment-manager deployments delete ${INFRA_ID}-bootstrap
```

7.11.17. Creating additional worker machines in GCP

You can create worker machines in Google Cloud Platform (GCP) for your cluster to use by launching individual instances discretely or by automated processes outside the cluster, such as auto scaling groups. You can also take advantage of the built-in cluster scaling mechanisms and the machine API in OpenShift Container Platform.

In this example, you manually launch one instance by using the Deployment Manager template. Additional instances can be launched by including additional resources of type **06_worker.py** in the file.

NOTE

If you do not use the provided Deployment Manager template to create your worker machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

Procedure

1. Copy the template from the **Deployment Manager template for worker machines** section of this topic and save it as **06_worker.py** on your computer. This template describes the worker machines that your cluster requires.
2. Export the variables that the resource definition uses.

- a. Export the subnet that hosts the compute machines:

```
$ export COMPUTE_SUBNET=`gcloud compute networks subnets describe
${HOST_PROJECT_COMPUTE_SUBNET} --region=${REGION} --project
${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT} --format json | jq -r
.selfLink`
```

- b. Export the email address for your service account:

```
$ export WORKER_SERVICE_ACCOUNT=`gcloud iam service-accounts list --filter
'email~^${INFRA_ID}-w@${PROJECT_NAME}.' --format json | jq -r '[0].email`
```

- c. Export the location of the compute machine Ignition config file:

```
$ export WORKER_IGNITION=`cat <installation_directory>/worker.ign`
```

3. Create a **06_worker.yaml** resource definition file:

```
$ cat <<EOF >06_worker.yaml
imports:
- path: 06_worker.py

resources:
- name: 'worker-0' 1
  type: 06_worker.py
  properties:
    infra_id: '${INFRA_ID}' 2
    zone: '${ZONE_0}' 3
    compute_subnet: '${COMPUTE_SUBNET}' 4
    image: '${CLUSTER_IMAGE}' 5
    machine_type: 'n1-standard-4' 6
    root_volume_size: '128'
    service_account_email: '${WORKER_SERVICE_ACCOUNT}' 7
    ignition: '${WORKER_IGNITION}' 8
- name: 'worker-1'
  type: 06_worker.py
  properties:
    infra_id: '${INFRA_ID}' 9
    zone: '${ZONE_1}' 10
    compute_subnet: '${COMPUTE_SUBNET}' 11
    image: '${CLUSTER_IMAGE}' 12
    machine_type: 'n1-standard-4' 13
    root_volume_size: '128'
```

```
service_account_email: '${WORKER_SERVICE_ACCOUNT}' 14
ignition: '${WORKER_IGNITION}' 15
EOF
```

- 1** **name** is the name of the worker machine, for example **worker-0**.
- 2** **9** **infra_id** is the **INFRA_ID** infrastructure name from the extraction step.
- 3** **10** **zone** is the zone to deploy the worker machine into, for example **us-central1-a**.
- 4** **11** **compute_subnet** is the **selfLink** URL to the compute subnet.
- 5** **12** **image** is the **selfLink** URL to the RHCOS image.
- 6** **13** **machine_type** is the machine type of the instance, for example **n1-standard-4**.
- 7** **14** **service_account_email** is the email address for the worker service account that you created.
- 8** **15** **ignition** is the contents of the **worker.ign** file.

4. Optional: If you want to launch additional instances, include additional resources of type **06_worker.py** in your **06_worker.yaml** resource definition file.
5. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-worker --config
06_worker.yaml
```

7.11.17.1. Deployment Manager template for worker machines

You can use the following Deployment Manager template to deploy the worker machines that you need for your OpenShift Container Platform cluster:

Example 7.18. 06_worker.py Deployment Manager template

```
def GenerateConfig(context):
    resources = [
        {
            'name': context.properties['infra_id'] + '-' + context.env['name'],
            'type': 'compute.v1.instance',
            'properties': {
                'disks': [
                    {
                        'autoDelete': True,
                        'boot': True,
                        'initializeParams': {
                            'diskSizeGb': context.properties['root_volume_size'],
                            'sourceImage': context.properties['image']
                        }
                    }
                ],
                'machineType': 'zones/' + context.properties['zone'] + '/machineTypes/' +
                context.properties['machine_type'],
                'metadata': {
                    'items': [

```

```

        'key': 'user-data',
        'value': context.properties['ignition']
    }]
},
'networkInterfaces': [
    'subnetwork': context.properties['compute_subnet']
],
'serviceAccounts': [
    'email': context.properties['service_account_email'],
    'scopes': ['https://www.googleapis.com/auth/cloud-platform']
],
'tags': {
    'items': [
        context.properties['infra_id'] + '-worker',
    ]
},
'zone': context.properties['zone']
}
]

return {'resources': resources}

```

7.11.18. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.9. Download and install the new version of **oc**.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.9 Linux Client** entry and save the file.
4. Unpack the archive:

```
$ tar xvzf <file>
```

5. Place the **oc** binary in a directory that is on your **PATH**.
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.9 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.

To check your **PATH**, open the command prompt and execute the following command:

```
C:> path
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
C:> oc <command>
```

Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.9 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.

To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

7.11.19. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The

kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

7.11.20. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.22.1
master-1	Ready	master	63m	v1.22.1
master-2	Ready	master	64m	v1.22.1

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

- Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-8b2br	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
csr-8vnps	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
...			

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

- If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

1 <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

NOTE

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	Pending
csr-c57lv	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	Pending
...			

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

1 <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs oc adm certificate approve
```

- After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	73m	v1.22.1
master-1	Ready	master	73m	v1.22.1

```
master-2 Ready master 74m v1.22.1
worker-0 Ready worker 11m v1.22.1
worker-1 Ready worker 11m v1.22.1
```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

7.11.21. Adding the ingress DNS records

DNS zone configuration is removed when creating Kubernetes manifests and generating Ignition configs. You must manually create DNS records that point at the ingress load balancer. You can create either a wildcard ***.apps.{baseDomain}**, or specific records. You can use A, CNAME, and other records per your requirements.

Prerequisites

- Configure a GCP account.
- Remove the DNS Zone configuration when creating Kubernetes manifests and generating Ignition configs.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.
- Create the worker machines.

Procedure

1. Wait for the Ingress router to create a load balancer and populate the **EXTERNAL-IP** field:

```
$ oc -n openshift-ingress get service router-default
```

Example output

NAME	TYPE	CLUSTER-IP	EXTERNAL-IP	PORT(S)	AGE
router-default	LoadBalancer	172.30.18.154	35.233.157.184	80:32288/TCP,443:31215/TCP	98

2. Add the A record to your zones:

- To use A records:

- i. Export the variable for the router IP address:

```
$ export ROUTER_IP=`oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}'`
```

- ii. Add the A record to the private zones:

```
$ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction add ${ROUTER_IP} --name
\*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone
${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account
${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone --
project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
```

- iii. For an external cluster, also add the A record to the public zones:

```
$ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME} -
-project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction add ${ROUTER_IP} --name
\*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone
${BASE_DOMAIN_ZONE_NAME} --project ${HOST_PROJECT} --account
${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction execute --zone
${BASE_DOMAIN_ZONE_NAME} --project ${HOST_PROJECT} --account
${HOST_PROJECT_ACCOUNT}
```

- To add explicit domains instead of using a wildcard, create entries for each of the cluster's current routes:

```
$ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}
{"\n"}{end}{end}' routes
```

Example output

```
oauth-openshift.apps.your.cluster.domain.example.com
console-openshift-console.apps.your.cluster.domain.example.com
downloads-openshift-console.apps.your.cluster.domain.example.com
alertmanager-main-openshift-monitoring.apps.your.cluster.domain.example.com
grafana-openshift-monitoring.apps.your.cluster.domain.example.com
prometheus-k8s-openshift-monitoring.apps.your.cluster.domain.example.com
```

7.11.22. Adding ingress firewall rules

The cluster requires several firewall rules. If you do not use a shared VPC, these rules are created by the ingress controller via the GCP cloud provider. When you use a shared VPC, you can either create cluster-wide firewall rules for all services now or create each rule based on events, when the cluster requests access. By creating each rule when the cluster requests access, you know exactly which firewall rules are required. By creating cluster-wide firewall rules, you can apply the same rule set across multiple clusters.

If you choose to create each rule based on events, you must create firewall rules after you provision the cluster and during the life of the cluster when the console notifies you that rules are missing. Events that are similar to the following event are displayed, and you must add the firewall rules that are required:

```
$ oc get events -n openshift-ingress --field-selector="reason=LoadBalancerManualChange"
```

Example output

```
Firewall change required by security admin: `gcloud compute firewall-rules create k8s-fw-a26e631036a3f46cba28f8df67266d55 --network example-network --description "{\"kubernetes.io/service-name\":\"\"}:\\"openshift-ingress/router-default\", \"kubernetes.io/service-ip\":\"35.237.236.234\"}\" --allow tcp:443,tcp:80 --source-ranges 0.0.0.0/0 --target-tags exempl-fqzq7-master,exampl-fqzq7-worker --project example-project`
```

If you encounter issues when creating these rule-based events, you can configure the cluster-wide firewall rules while your cluster is running.

7.11.22.1. Creating cluster-wide firewall rules for a shared VPC in GCP

You can create cluster-wide firewall rules to allow the access that the OpenShift Container Platform cluster requires.

WARNING

If you do not choose to create firewall rules based on cluster events, you must create cluster-wide firewall rules.

Prerequisites

- You exported the variables that the Deployment Manager templates require to deploy your cluster.
- You created the networking and load balancing components in GCP that your cluster requires.

Procedure

1. Add a single firewall rule to allow the Google Cloud Engine health checks to access all of the services. This rule enables the ingress load balancers to determine the health status of their instances.

```
$ gcloud compute firewall-rules create --allow='tcp:30000-32767,udp:30000-32767' --network="${CLUSTER_NETWORK}" --source-ranges='130.211.0.0/22,35.191.0.0/16,209.85.152.0/22,209.85.204.0/22' --target-tags="${INFRA_ID}-master,${INFRA_ID}-worker" ${INFRA_ID}-ingress-hc --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
```

2. Add a single firewall rule to allow access to all cluster services:

- For an external cluster:

```
$ gcloud compute firewall-rules create --allow='tcp:80,tcp:443' --
network="${CLUSTER_NETWORK}" --source-ranges="0.0.0.0/0" --target-
tags="${INFRA_ID}-master,${INFRA_ID}-worker" ${INFRA_ID}-ingress --
account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
```

- For a private cluster:

```
$ gcloud compute firewall-rules create --allow='tcp:80,tcp:443' --
network="${CLUSTER_NETWORK}" --source-ranges=${NETWORK_CIDR} --target-
tags="${INFRA_ID}-master,${INFRA_ID}-worker" ${INFRA_ID}-ingress --
account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
```

Because this rule only allows traffic on TCP ports **80** and **443**, ensure that you add all the ports that your services use.

7.11.23. Completing a GCP installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Google Cloud Platform (GCP) user-provisioned infrastructure, you can monitor the cluster events until the cluster is ready.

Prerequisites

- Deploy the bootstrap machine for an OpenShift Container Platform cluster on user-provisioned GCP infrastructure.
- Install the **oc** CLI and log in.

Procedure

1. Complete the cluster installation:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete ①
```

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

2. Observe the running state of your cluster.

a. Run the following command to view the current cluster version and status:

```
$ oc get clusterversion
```

Example output

NAME	VERSION	AVAILABLE	PROGRESSING	SINCE	STATUS
version	False	True	24m	Working towards 4.5.4: 99% complete	

b. Run the following command to view the Operators managed on the control plane by the Cluster Version Operator (CVO):

```
$ oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.5.4	True	False	False 7m56s
cloud-credential	4.5.4	True	False	False 31m
cluster-autoscaler	4.5.4	True	False	False 16m
console	4.5.4	True	False	False 10m
csi-snapshot-controller	4.5.4	True	False	False 16m
dns	4.5.4	True	False	False 22m
etcd	4.5.4	False	False	False 25s
image-registry	4.5.4	True	False	False 16m
ingress	4.5.4	True	False	False 16m
insights	4.5.4	True	False	False 17m
kube-apiserver	4.5.4	True	False	False 19m
kube-controller-manager	4.5.4	True	False	False 20m

openshift-service-ca			service-serving-cert-signer-6445fc9c6-wqdqn
1/1	Running	0	35m
openshift-service-catalog-apiserver-operator			openshift-service-catalog-apiserver-
operator-549f44668b-b5q2w	1/1	Running	0 32m
openshift-service-catalog-controller-manager-operator			openshift-service-catalog-
controller-manager-operator-b78cr2lnm	1/1	Running	0 31m

When the current cluster version is **AVAILABLE**, the installation is complete.

7.11.24. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

7.11.25. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).

7.12. INSTALLING A CLUSTER ON GCP IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.9, you can install a cluster on Google Cloud Platform (GCP) that uses infrastructure that you provide and an internal mirror of the installation release content.

IMPORTANT

While you can install an OpenShift Container Platform cluster by using mirrored installation release content, your cluster still requires internet access to use the GCP APIs.

The steps for performing a user-provided infrastructure install are outlined here. Several [Deployment Manager](#) templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods.

IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several Deployment Manager templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods; the templates are just an example.

7.12.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [created a registry on your mirror host](#) and obtained the **imageContentSources** data for your version of OpenShift Container Platform.

IMPORTANT

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to. While you might need to grant access to more sites, you must grant access to [*.googleapis.com](#) and [accounts.google.com](#).
- If the cloud identity and access management (IAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the **kube-system** namespace, you can [manually create and maintain IAM credentials](#).

7.12.2. About installations in restricted networks

In OpenShift Container Platform 4.9, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be

completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require internet access, so you might still require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

7.12.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

7.12.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

7.12.4. Configuring your GCP project

Before you can install OpenShift Container Platform, you must configure a Google Cloud Platform (GCP) project to host it.

7.12.4.1. Creating a GCP project

To install OpenShift Container Platform, you must create a project in your Google Cloud Platform (GCP) account to host the cluster.

Procedure

- Create a project to host your OpenShift Container Platform cluster. See [Creating and Managing Projects](#) in the GCP documentation.

IMPORTANT

Your GCP project must use the Premium Network Service Tier if you are using installer-provisioned infrastructure. The Standard Network Service Tier is not supported for clusters installed using the installation program. The installation program configures internal load balancing for the **api-int.<cluster_name>. <base_domain>** URL; the Premium Tier is required for internal load balancing.

7.12.4.2. Enabling API services in GCP

Your Google Cloud Platform (GCP) project requires access to several API services to complete OpenShift Container Platform installation.

Prerequisites

- You created a project to host your cluster.

Procedure

- Enable the following required API services in the project that hosts your cluster. See [Enabling services](#) in the GCP documentation.

Table 7.42. Required API services

API service	Console service name
Compute Engine API	compute.googleapis.com
Google Cloud APIs	cloudapis.googleapis.com
Cloud Resource Manager API	cloudresourcemanager.googleapis.com
Google DNS API	dns.googleapis.com
IAM Service Account Credentials API	iamcredentials.googleapis.com
Identity and Access Management (IAM) API	iam.googleapis.com

API service	Console service name
Service Management API	servicemanagement.googleapis.com
Service Usage API	serviceusage.googleapis.com
Google Cloud Storage JSON API	storage-api.googleapis.com
Cloud Storage	storage-component.googleapis.com

7.12.4.3. Configuring DNS for GCP

To install OpenShift Container Platform, the Google Cloud Platform (GCP) account you use must have a dedicated public hosted zone in the same project that you host the OpenShift Container Platform cluster. This zone must be authoritative for the domain. The DNS service provides cluster DNS resolution and name lookup for external connections to the cluster.

Procedure

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through GCP or another source.

NOTE

If you purchase a new domain, it can take time for the relevant DNS changes to propagate. For more information about purchasing domains through Google, see [Google Domains](#).

2. Create a public hosted zone for your domain or subdomain in your GCP project. See [Creating public zones](#) in the GCP documentation.
Use an appropriate root domain, such as **openshiftcorp.com**, or subdomain, such as **clusters.openshiftcorp.com**.
3. Extract the new authoritative name servers from the hosted zone records. See [Look up your Cloud DNS name servers](#) in the GCP documentation.
You typically have four name servers.
4. Update the registrar records for the name servers that your domain uses. For example, if you registered your domain to Google Domains, see the following topic in the Google Domains Help: [How to switch to custom name servers](#).
5. If you migrated your root domain to Google Cloud DNS, migrate your DNS records. See [Migrating to Cloud DNS](#) in the GCP documentation.
6. If you use a subdomain, follow your company's procedures to add its delegation records to the parent domain. This process might include a request to your company's IT department or the division that controls the root domain and DNS services for your company.

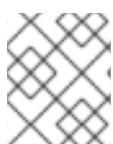

7.12.4.4. GCP account limits

The OpenShift Container Platform cluster uses a number of Google Cloud Platform (GCP) components, but the default [Quotas](#) do not affect your ability to install a default OpenShift Container Platform cluster.

A default cluster, which contains three compute and three control plane machines, uses the following resources. Note that some resources are required only during the bootstrap process and are removed after the cluster deploys.

Table 7.43. GCP resources used in a default cluster

Service	Component	Location	Total resources required	Resources removed after bootstrap
Service account	IAM	Global	5	0
Firewall rules	Networking	Global	11	1
Forwarding rules	Compute	Global	2	0
Health checks	Compute	Global	2	0
Images	Compute	Global	1	0
Networks	Networking	Global	1	0
Routers	Networking	Global	1	0
Routes	Networking	Global	2	0
Subnetworks	Compute	Global	2	0
Target pools	Networking	Global	2	0

NOTE

If any of the quotas are insufficient during installation, the installation program displays an error that states both which quota was exceeded and the region.

Be sure to consider your actual cluster size, planned cluster growth, and any usage from other clusters that are associated with your account. The CPU, static IP addresses, and persistent disk SSD (storage) quotas are the ones that are most likely to be insufficient.

If you plan to deploy your cluster in one of the following regions, you will exceed the maximum storage quota and are likely to exceed the CPU quota limit:

- **asia-east2**
- **asia-northeast2**
- **asia-south1**

- **australia-southeast1**
- **europe-north1**
- **europe-west2**
- **europe-west3**
- **europe-west6**
- **northamerica-northeast1**
- **southamerica-east1**
- **us-west2**

You can increase resource quotas from the [GCP console](#), but you might need to file a support ticket. Be sure to plan your cluster size early so that you can allow time to resolve the support ticket before you install your OpenShift Container Platform cluster.

7.12.4.5. Creating a service account in GCP

OpenShift Container Platform requires a Google Cloud Platform (GCP) service account that provides authentication and authorization to access data in the Google APIs. If you do not have an existing IAM service account that contains the required roles in your project, you must create one.

Prerequisites

- You created a project to host your cluster.

Procedure

1. Create a service account in the project that you use to host your OpenShift Container Platform cluster. See [Creating a service account](#) in the GCP documentation.
2. Grant the service account the appropriate permissions. You can either grant the individual permissions that follow or assign the **Owner** role to it. See [Granting roles to a service account for specific resources](#).

NOTE

While making the service account an owner of the project is the easiest way to gain the required permissions, it means that service account has complete control over the project. You must determine if the risk that comes from offering that power is acceptable.

3. Create the service account key in JSON format. See [Creating service account keys](#) in the GCP documentation.
The service account key is required to create a cluster.

7.12.4.5.1. Required GCP permissions

When you attach the **Owner** role to the service account that you create, you grant that service account all permissions, including those that are required to install OpenShift Container Platform. To deploy an OpenShift Container Platform cluster, the service account requires the following permissions. If you

deploy your cluster into an existing VPC, the service account does not require certain networking permissions, which are noted in the following lists:

Required roles for the installation program

- Compute Admin
- Security Admin
- Service Account Admin
- Service Account User
- Storage Admin

Required roles for creating network resources during installation

- DNS Administrator

Required roles for user-provisioned GCP infrastructure

- Deployment Manager Editor
- Service Account Key Admin

Optional roles

For the cluster to create new limited credentials for its Operators, add the following role:

- Service Account Key Admin

The roles are applied to the service accounts that the control plane and compute machines use:

Table 7.44. GCP service account permissions

Account	Roles
Control Plane	roles/compute.instanceAdmin
	roles/compute.networkAdmin
	roles/compute.securityAdmin
	roles/storage.admin
	roles/iam.serviceAccountUser
Compute	roles/compute.viewer
	roles/storage.admin

7.12.4.6. Supported GCP regions

You can deploy an OpenShift Container Platform cluster to the following Google Cloud Platform (GCP) regions:

- **asia-east1** (Changhua County, Taiwan)
- **asia-east2** (Hong Kong)
- **asia-northeast1** (Tokyo, Japan)
- **asia-northeast2** (Osaka, Japan)
- **asia-northeast3** (Seoul, South Korea)
- **asia-south1** (Mumbai, India)
- **asia-southeast1** (Jurong West, Singapore)
- **asia-southeast2** (Jakarta, Indonesia)
- **australia-southeast1** (Sydney, Australia)
- **europe-central2** (Warsaw, Poland)
- **europe-north1** (Hamina, Finland)
- **europe-west1** (St. Ghislain, Belgium)
- **europe-west2** (London, England, UK)
- **europe-west3** (Frankfurt, Germany)
- **europe-west4** (Eemshaven, Netherlands)
- **europe-west6** (Zürich, Switzerland)
- **northamerica-northeast1** (Montréal, Québec, Canada)
- **southamerica-east1** (São Paulo, Brazil)
- **us-central1** (Council Bluffs, Iowa, USA)
- **us-east1** (Moncks Corner, South Carolina, USA)
- **us-east4** (Ashburn, Northern Virginia, USA)
- **us-west1** (The Dalles, Oregon, USA)
- **us-west2** (Los Angeles, California, USA)
- **us-west3** (Salt Lake City, Utah, USA)
- **us-west4** (Las Vegas, Nevada, USA)

7.12.4.7. Installing and configuring CLI tools for GCP

To install OpenShift Container Platform on Google Cloud Platform (GCP) using user-provisioned infrastructure, you must install and configure the CLI tools for GCP.

Prerequisites

- You created a project to host your cluster.
- You created a service account and granted it the required permissions.

Procedure

1. Install the following binaries in **\$PATH**:

- **gcloud**
- **gsutil**

See [Install the latest Cloud SDK version](#) in the GCP documentation.

2. Authenticate using the **gcloud** tool with your configured service account.

See [Authorizing with a service account](#) in the GCP documentation.

7.12.5. Creating the installation files for GCP

To install OpenShift Container Platform on Google Cloud Platform (GCP) using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and customize the **install-config.yaml** file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate **var** partition during the preparation phases of installation.

7.12.5.1. Optional: Creating a separate /var partition

It is recommended that disk partitioning for OpenShift Container Platform be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the **/var** partition or a subdirectory of **/var**. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a **/var** directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because **/var** must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate **/var** partition by creating a machine config manifest that is inserted during the **openshift-install** preparation phases of an OpenShift Container Platform installation.

IMPORTANT

If you follow the steps to create a separate **/var** partition in this procedure, it is not necessary to create the Kubernetes manifest and Ignition config files again as described later in this section.

Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

```
$ mkdir $HOME/clusterconfig
```

2. Run **openshift-install** to create a set of files in the **manifest** and **openshift** subdirectories. Answer the system questions as you are prompted:

```
$ openshift-install create manifests --dir $HOME/clusterconfig
```

Example output

```
? SSH Public Key ...
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: $HOME/clusterconfig/manifests and
$HOME/clusterconfig/openshift
```

3. Optional: Confirm that the installation program created manifests in the **clusterconfig/openshift** directory:

```
$ ls $HOME/clusterconfig/openshift/
```

Example output

```
99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...
...
```

4. Create a Butane config that configures the additional partition. For example, name the file **\$HOME/clusterconfig/98-var-partition.bu**, change the disk device name to the name of the storage device on the **worker** systems, and set the storage size as appropriate. This example places the **/var** directory on a separate partition:

```
variant: openshift
version: 4.9.0
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
storage:
  disks:
    - device: /dev/<device_name> ①
  partitions:
```

```

- label: var
  start_mib: <partition_start_offset> ②
  size_mib: <partition_size> ③
  filesystems:
    - device: /dev/disk/by-partlabel/var
      path: /var
      format: xfs
      mount_options: [defaults, prjquota] ④
      with_mount_unit: true

```

- ① The storage device name of the disk that you want to partition.
- ② When adding a data partition to the boot disk, a minimum value of 25000 MiB (Mebibytes) is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
- ③ The size of the data partition in mebibytes.
- ④ The **prjquota** mount option must be enabled for filesystems used for container storage.

NOTE

When creating a separate **/var** partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

5. Create a manifest from the Butane config and save it to the **clusterconfig/openshift** directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

6. Run **openshift-install** again to create Ignition configs from a set of files in the **manifest** and **openshift** subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

7.12.5.2. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

- Have the **imageContentSources** values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.
- Obtain service principal permissions at the subscription level.

Procedure

1. Create the **install-config.yaml** file.
 - a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir=<installation_directory> ①
```

- ① For **<installation_directory>**, specify the directory name to store the files that the installation program creates.

IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

- b. At the prompts, provide the configuration details for your cloud:
 - i. Optional: Select an SSH key to use to access your cluster machines.
 - ii. Select **gcp** as the platform to target.
 - iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.
 - iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.
 - v. Select the region to deploy the cluster to.
 - vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
 - vii. Enter a descriptive name for your cluster.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- viii. Paste the pull secret that you obtained from the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site.

2. Edit the **install-config.yaml** file to provide the additional information that is required for an installation in a restricted network.

 - a. Update the **pullSecret** value to contain the authentication information for your registry:

```
pullSecret: '{"auths": {"<mirror_host_name>:5000": {"auth": "<credentials>", "email": "you@example.com"}}}'
```

For **<mirror_host_name>**, specify the registry domain name that you specified in the certificate for your mirror registry, and for **<credentials>**, specify the base64-encoded user name and password for your mirror registry.

- b. Add the **additionalTrustBundle** parameter and value.

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

- c. Define the network and subnets for the VPC to install the cluster in under the parent **platform.qcp** field:

```
network: <existing_vpc>
controlPlaneSubnet: <control_plane_subnet>
computeSubnet: <compute_subnet>
```

For **platform.gcp.network**, specify the name for the existing Google VPC. For **platform.gcp.controlPlaneSubnet** and **platform.gcp.computeSubnet**, specify the existing subnets to deploy the control plane machines and compute machines, respectively.

- d. Add the image content resources, which look like this excerpt:

```
imageContentSources:  
- mirrors:  
  - <mirror_host_name>:5000/<repo_name>/release  
    source: quay.example.com/openshift-release-dev/ocp-release  
- mirrors:  
  - <mirror_host_name>:5000/<repo_name>/release  
    source: registry.example.com/ocp/release
```

To complete these values, use the **imageContentSources** that you recorded during mirror registry creation.

3. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.
 4. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

7.12.5.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

- If your cluster is on AWS, you added the **ec2.<region>.amazonaws.com**, **elasticloadbalancing.<region>.amazonaws.com**, and **s3.<region>.amazonaws.com** endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ①
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
  noProxy: example.com ③
  additionalTrustBundle: | ④
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
  ...
  ...
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**. If you use an MITM transparent proxy network that does not require additional CAs, you must not specify an **httpsProxy** value.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpsProxy** value.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace to hold the additional CA certificates. If you provide **additionalTrustBundle** and at least one proxy setting, the **Proxy** object is configured to reference the **user-ca-bundle** config map in the **trustedCA** field. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges the contents specified for the **trustedCA** parameter with the RHCOS trust bundle. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE

The installation program does not support the proxy **readinessEndpoints** field.

- 2 Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

7.12.5.4. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the **install-config.yaml** installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

Example output

```
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift
```

- 1 For **<installation_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
```

By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Check that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yaml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:

- a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
 - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
 - c. Save and exit the file.
5. Optional: If you do not want [the Ingress Operator](#) to create DNS records on your behalf, remove the **privateZone** and **publicZone** sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

```
apiVersion: config.openshift.io/v1
kind: DNS
metadata:
  creationTimestamp: null
  name: cluster
spec:
  baseDomain: example.openshift.com
  privateZone: ①
    id: mycluster-100419-private-zone
  publicZone: ②
    id: example.openshift.com
status: {}
```

① ② Remove this section completely.

If you do so, you must add ingress DNS records manually in a later step.

6. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory> ①
```

① For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the `./<installation_directory>/auth` directory:

Additional resources

- [Optional: Adding the ingress DNS records](#)

7.12.6. Exporting common variables

7.12.6.1. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in Google Cloud Platform (GCP). The infrastructure name is also used to locate the appropriate GCP resources during an OpenShift Container Platform installation. The provided Deployment Manager templates contain references to this infrastructure name, so you must extract it.

Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the **jq** package.

Procedure

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```
$ jq -r .infraID <installation_directory>/metadata.json ①
```

- ① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

Example output

```
openshift-vw9j6 ①
```

- ① The output of this command is your cluster name and a random string.

7.12.6.2. Exporting common variables for Deployment Manager templates

You must export a common set of variables that are used with the provided Deployment Manager templates used to assist in completing a user-provided infrastructure install on Google Cloud Platform (GCP).

NOTE

Specific Deployment Manager templates can also require additional exported variables, which are detailed in their related procedures.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Generate the Ignition config files for your cluster.
- Install the **jq** package.

Procedure

1. Export the following common variables to be used by the provided Deployment Manager templates:

```
$ export BASE_DOMAIN='<base_domain>'  
$ export BASE_DOMAIN_ZONE_NAME='<base_domain_zone_name>'  
$ export NETWORK_CIDR='10.0.0.0/16'  
$ export MASTER_SUBNET_CIDR='10.0.0.0/17'  
$ export WORKER_SUBNET_CIDR='10.0.128.0/17'  
  
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①  
$ export CLUSTER_NAME=`jq -r .clusterName <installation_directory>/metadata.json`  
$ export INFRA_ID=`jq -r .infralD <installation_directory>/metadata.json`  
$ export PROJECT_NAME=`jq -r .gcp.projectID <installation_directory>/metadata.json`  
$ export REGION=`jq -r .gcp.region <installation_directory>/metadata.json`
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

7.12.7. Creating a VPC in GCP

You must create a VPC in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. You can customize the VPC to meet your requirements. One way to create the VPC is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.

Procedure

1. Copy the template from the **Deployment Manager template for the VPC** section of this topic and save it as **01_vpc.py** on your computer. This template describes the VPC that your cluster requires.
2. Create a **01_vpc.yaml** resource definition file:

```
$ cat <<EOF >01_vpc.yaml  
imports:  
- path: 01_vpc.py  
  
resources:  
- name: cluster-vpc  
  type: 01_vpc.py
```

```

properties:
  infra_id: '${INFRA_ID}' 1
  region: '${REGION}' 2
  master_subnet_cidr: '${MASTER_SUBNET_CIDR}' 3
  worker_subnet_cidr: '${WORKER_SUBNET_CIDR}' 4
EOF

```

- 1** **infra_id** is the **INFRA_ID** infrastructure name from the extraction step.
- 2** **region** is the region to deploy the cluster into, for example **us-central1**.
- 3** **master_subnet_cidr** is the CIDR for the master subnet, for example **10.0.0.0/17**.
- 4** **worker_subnet_cidr** is the CIDR for the worker subnet, for example **10.0.128.0/17**.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-vpc --config 01_vpc.yaml
```

7.12.7.1. Deployment Manager template for the VPC

You can use the following Deployment Manager template to deploy the VPC that you need for your OpenShift Container Platform cluster:

Example 7.19. 01_vpc.py Deployment Manager template

```

def GenerateConfig(context):
    resources = [
        {
            'name': context.properties['infra_id'] + '-network',
            'type': 'compute.v1.network',
            'properties': {
                'region': context.properties['region'],
                'autoCreateSubnetworks': False
            }
        },
        {
            'name': context.properties['infra_id'] + '-master-subnet',
            'type': 'compute.v1.subnetwork',
            'properties': {
                'region': context.properties['region'],
                'network': '$(ref.' + context.properties['infra_id'] + '-network.selfLink)',
                'ipCidrRange': context.properties['master_subnet_cidr']
            }
        },
        {
            'name': context.properties['infra_id'] + '-worker-subnet',
            'type': 'compute.v1.subnetwork',
            'properties': {
                'region': context.properties['region'],
                'network': '$(ref.' + context.properties['infra_id'] + '-network.selfLink)',
                'ipCidrRange': context.properties['worker_subnet_cidr']
            }
        },
        {
            'name': context.properties['infra_id'] + '-router',
            'type': 'compute.v1.router',

```

```

'properties': {
    'region': context.properties['region'],
    'network': '$(ref.' + context.properties['infra_id'] + '-network.selfLink)',
    'nats': [
        {
            'name': context.properties['infra_id'] + '-nat-master',
            'natIpAllocateOption': 'AUTO_ONLY',
            'minPortsPerVm': 7168,
            'sourceSubnetworkIpRangesToNat': 'LIST_OF_SUBNETWORKS',
            'subnetworks': [
                {
                    'name': '$(ref.' + context.properties['infra_id'] + '-master-subnet.selfLink)',
                    'sourceIpRangesToNat': ['ALL_IP_RANGES']
                }
            ]
        },
        {
            'name': context.properties['infra_id'] + '-nat-worker',
            'natIpAllocateOption': 'AUTO_ONLY',
            'minPortsPerVm': 512,
            'sourceSubnetworkIpRangesToNat': 'LIST_OF_SUBNETWORKS',
            'subnetworks': [
                {
                    'name': '$(ref.' + context.properties['infra_id'] + '-worker-subnet.selfLink)',
                    'sourceIpRangesToNat': ['ALL_IP_RANGES']
                }
            ]
        }
    ]
}

return {'resources': resources}

```

7.12.8. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

7.12.8.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

7.12.8.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

Table 7.45. Ports used for all-machine to all-machine communications

Protocol	Port	Description
ICMP	N/A	Network reachability tests
TCP	1936	Metrics
	9000-9999	Host level services, including the node exporter on ports 9100-9101 and the Cluster Version Operator on port 9099 .
	10250-10259	The default ports that Kubernetes reserves
	10256	openshift-sdn
UDP	4789	VXLAN and Geneve
	6081	VXLAN and Geneve
	9000-9999	Host level services, including the node exporter on ports 9100-9101 .
TCP/UDP	30000-32767	Kubernetes node port

Table 7.46. Ports used for all-machine to control plane communications

Protocol	Port	Description
TCP	6443	Kubernetes API

Table 7.47. Ports used for control plane machine to control plane machine communications

Protocol	Port	Description
TCP	2379-2380	etcd server and peer ports

7.12.9. Creating load balancers in GCP

You must configure load balancers in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure

- Copy the template from the **Deployment Manager template for the internal load balancer** section of this topic and save it as **02_lb_int.py** on your computer. This template describes the internal load balancing objects that your cluster requires.
- For an external cluster, also copy the template from the **Deployment Manager template for the external load balancer** section of this topic and save it as **02_lb_ext.py** on your computer. This template describes the external load balancing objects that your cluster requires.
- Export the variables that the deployment template uses:
 - Export the cluster network location:

```
$ export CLUSTER_NETWORK=(`gcloud compute networks describe ${INFRA_ID}-network --format json | jq -r .selfLink`)
```
 - Export the control plane subnet location:

```
$ export CONTROL_SUBNET=(`gcloud compute networks subnets describe ${INFRA_ID}-master-subnet --region=${REGION} --format json | jq -r .selfLink`)
```
 - Export the three zones that the cluster uses:

```
$ export ZONE_0=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[0] | cut -d "/" -f9`)
```

```
$ export ZONE_1=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[1] | cut -d "/" -f9`)
```

```
$ export ZONE_2=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[2] | cut -d "/" -f9`)
```
- Create a **02_infra.yaml** resource definition file:

```
$ cat <<EOF >02_infra.yaml
imports:
- path: 02_lb_ext.py
- path: 02_lb_int.py ①
resources:
- name: cluster-lb-ext ②
  type: 02_lb_ext.py
  properties:
    infra_id: '${INFRA_ID}' ③
    region: '${REGION}' ④
- name: cluster-lb-int
```

```

type: 02_lb_int.py
properties:
  cluster_network: '${CLUSTER_NETWORK}'
  control_subnet: '${CONTROL_SUBNET}' 5
  infra_id: '${INFRA_ID}'
  region: '${REGION}'
  zones: 6
    - '${ZONE_0}'
    - '${ZONE_1}'
    - '${ZONE_2}'
EOF

```

1 **2** Required only when deploying an external cluster.

3 **infra_id** is the **INFRA_ID** infrastructure name from the extraction step.

4 **region** is the region to deploy the cluster into, for example **us-central1**.

5 **control_subnet** is the URI to the control subnet.

6 **zones** are the zones to deploy the control plane instances into, like **us-east1-b**, **us-east1-c**, and **us-east1-d**.

5. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-infra --config 02_infra.yaml
```

6. Export the cluster IP address:

```
$ export CLUSTER_IP=`gcloud compute addresses describe ${INFRA_ID}-cluster-ip --region=${REGION} --format json | jq -r .address`
```

7. For an external cluster, also export the cluster public IP address:

```
$ export CLUSTER_PUBLIC_IP=`gcloud compute addresses describe ${INFRA_ID}-cluster-public-ip --region=${REGION} --format json | jq -r .address`
```

7.12.9.1. Deployment Manager template for the external load balancer

You can use the following Deployment Manager template to deploy the external load balancer that you need for your OpenShift Container Platform cluster:

Example 7.20. 02_lb_ext.py Deployment Manager template

```

def GenerateConfig(context):

  resources = [
    'name': context.properties['infra_id'] + '-cluster-public-ip',
    'type': 'compute.v1.address',
    'properties': {
      'region': context.properties['region']
    }
  ],

```

```

# Refer to docs/dev/kube-apiserver-health-check.md on how to correctly setup health check
probe for kube-apiserver
  'name': context.properties['infra_id'] + '-api-http-health-check',
  'type': 'compute.v1.httpHealthCheck',
  'properties': {
    'port': 6080,
    'requestPath': '/readyz'
  },
  {
    'name': context.properties['infra_id'] + '-api-target-pool',
    'type': 'compute.v1.targetPool',
    'properties': {
      'region': context.properties['region'],
      'healthChecks': ['$(ref.' + context.properties['infra_id'] + '-api-http-health-check.selfLink)'],
      'instances': []
    }
  },
  {
    'name': context.properties['infra_id'] + '-api-forwarding-rule',
    'type': 'compute.v1.forwardingRule',
    'properties': {
      'region': context.properties['region'],
      'IPAddress': '$(ref.' + context.properties['infra_id'] + '-cluster-public-ip.selfLink)',
      'target': '$(ref.' + context.properties['infra_id'] + '-api-target-pool.selfLink)',
      'portRange': '6443'
    }
  }
]

return {'resources': resources}

```

7.12.9.2. Deployment Manager template for the internal load balancer

You can use the following Deployment Manager template to deploy the internal load balancer that you need for your OpenShift Container Platform cluster:

Example 7.21. 02_lb_int.py Deployment Manager template

```

def GenerateConfig(context):

  backends = []
  for zone in context.properties['zones']:
    backends.append({
      'group': '$(ref.' + context.properties['infra_id'] + '-master-' + zone + '-instance-group' +
      '.selfLink)'
    })

  resources = [
    {
      'name': context.properties['infra_id'] + '-cluster-ip',
      'type': 'compute.v1.address',
      'properties': {
        'addressType': 'INTERNAL',
        'region': context.properties['region'],
        'subnetwork': context.properties['control_subnet']
      }
    },
    {

```

```

# Refer to docs/dev/kube-apiserver-health-check.md on how to correctly setup health check
probe for kube-apiserver
  'name': context.properties['infra_id'] + '-api-internal-health-check',
  'type': 'compute.v1.healthCheck',
  'properties': {
    'httpsHealthCheck': {
      'port': 6443,
      'requestPath': '/readyz'
    },
    'type': "HTTPS"
  }
}, {
  'name': context.properties['infra_id'] + '-api-internal-backend-service',
  'type': 'compute.v1.regionBackendService',
  'properties': {
    'backends': backends,
    'healthChecks': ['$ref.' + context.properties['infra_id'] + '-api-internal-health-
check.selfLink'],
    'loadBalancingScheme': 'INTERNAL',
    'region': context.properties['region'],
    'protocol': 'TCP',
    'timeoutSec': 120
  }
}, {
  'name': context.properties['infra_id'] + '-api-internal-forwarding-rule',
  'type': 'compute.v1.forwardingRule',
  'properties': {
    'backendService': '$(ref.' + context.properties['infra_id'] + '-api-internal-backend-
service.selfLink)',
    'IPAddress': '$(ref.' + context.properties['infra_id'] + '-cluster-ip.selfLink)',
    'loadBalancingScheme': 'INTERNAL',
    'ports': [6443,22623],
    'region': context.properties['region'],
    'subnetwork': context.properties['control_subnet']
  }
}
]

for zone in context.properties['zones']:
  resources.append({
    'name': context.properties['infra_id'] + '-master-' + zone + '-instance-group',
    'type': 'compute.v1.instanceGroup',
    'properties': {
      'namedPorts': [
        {
          'name': 'ignition',
          'port': 22623
        },
        {
          'name': 'https',
          'port': 6443
        }
      ],
      'network': context.properties['cluster_network'],
      'zone': zone
    }
  })

```

```

    })
return {'resources': resources}

```

You will need this template in addition to the **02_lb_ext.py** template when you create an external cluster.

7.12.10. Creating a private DNS zone in GCP

You must configure a private DNS zone in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create this component is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure

- Copy the template from the **Deployment Manager template for the private DNS** section of this topic and save it as **02_dns.py** on your computer. This template describes the private DNS objects that your cluster requires.
- Create a **02_dns.yaml** resource definition file:

```

$ cat <<EOF >02_dns.yaml
imports:
- path: 02_dns.py

resources:
- name: cluster-dns
  type: 02_dns.py
  properties:
    infra_id: '${INFRA_ID}' 1
    cluster_domain: '${CLUSTER_NAME}.${BASE_DOMAIN}' 2
    cluster_network: '${CLUSTER_NETWORK}' 3
EOF

```

1 **infra_id** is the **INFRA_ID** infrastructure name from the extraction step.

2 **cluster_domain** is the domain for the cluster, for example **openshift.example.com**.

- 3** **cluster_network** is the **selfLink** URL to the cluster network.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-dns --config 02_dns.yaml
```

4. The templates do not create DNS entries due to limitations of Deployment Manager, so you must create them manually:

- a. Add the internal DNS entries:

```
$ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone
$ gcloud dns record-sets transaction add ${CLUSTER_IP} --name
api.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone ${INFRA_ID}-
private-zone
$ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api-
int.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone ${INFRA_ID}-
private-zone
$ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone
```

- b. For an external cluster, also add the external DNS entries:

```
$ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction add ${CLUSTER_PUBLIC_IP} --name
api.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone
${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction execute --zone ${BASE_DOMAIN_ZONE_NAME}
```

7.12.10.1. Deployment Manager template for the private DNS

You can use the following Deployment Manager template to deploy the private DNS that you need for your OpenShift Container Platform cluster:

Example 7.22. 02_dns.py Deployment Manager template

```
def GenerateConfig(context):
    resources = [
        {
            'name': context.properties['infra_id'] + '-private-zone',
            'type': 'dns.v1.managedZone',
            'properties': {
                'description': '',
                'dnsName': context.properties['cluster_domain'] + '',
                'visibility': 'private',
                'privateVisibilityConfig': {
                    'networks': [
                        {
                            'networkUrl': context.properties['cluster_network']
                        }
                    ]
                }
            }
        }
    ]
```

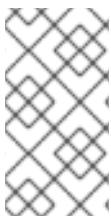

```

    }]
return {'resources': resources}

```

7.12.11. Creating firewall rules in GCP

You must create firewall rules in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure

- Copy the template from the **Deployment Manager template for firewall rules** section of this topic and save it as **03_firewall.py** on your computer. This template describes the security groups that your cluster requires.
- Create a **03_firewall.yaml** resource definition file:

```

$ cat <<EOF >03_firewall.yaml
imports:
- path: 03_firewall.py

resources:
- name: cluster-firewall
  type: 03_firewall.py
  properties:
    allowed_external_cidr: '0.0.0.0/0' ①
    infra_id: '${INFRA_ID}' ②
    cluster_network: '${CLUSTER_NETWORK}' ③
    network_cidr: '${NETWORK_CIDR}' ④
EOF

```

- allowed_external_cidr** is the CIDR range that can access the cluster API and SSH to the bootstrap host. For an internal cluster, set this value to **\${NETWORK_CIDR}**.
- infra_id** is the **INFRA_ID** infrastructure name from the extraction step.
- cluster_network** is the **selfLink** URL to the cluster network.

- 4 **network_cidr** is the CIDR of the VPC network, for example **10.0.0.0/16**.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-firewall --config
03_firewall.yaml
```

7.12.11.1. Deployment Manager template for firewall rules

You can use the following Deployment Manager template to deploy the firewall rules that you need for your OpenShift Container Platform cluster:

Example 7.23. 03_firewall.py Deployment Manager template

```
def GenerateConfig(context):
    resources = [
        {
            'name': context.properties['infra_id'] + '-bootstrap-in-ssh',
            'type': 'compute.v1.firewall',
            'properties': {
                'network': context.properties['cluster_network'],
                'allowed': [
                    {
                        'IPProtocol': 'tcp',
                        'ports': ['22']
                    }
                ],
                'sourceRanges': [context.properties['allowed_external_cidr']],
                'targetTags': [context.properties['infra_id'] + '-bootstrap']
            }
        },
        {
            'name': context.properties['infra_id'] + '-api',
            'type': 'compute.v1.firewall',
            'properties': {
                'network': context.properties['cluster_network'],
                'allowed': [
                    {
                        'IPProtocol': 'tcp',
                        'ports': ['6443']
                    }
                ],
                'sourceRanges': [context.properties['allowed_external_cidr']],
                'targetTags': [context.properties['infra_id'] + '-master']
            }
        },
        {
            'name': context.properties['infra_id'] + '-health-checks',
            'type': 'compute.v1.firewall',
            'properties': {
                'network': context.properties['cluster_network'],
                'allowed': [
                    {
                        'IPProtocol': 'tcp',
                        'ports': ['6080', '6443', '22624']
                    }
                ],
                'sourceRanges': ['35.191.0.0/16', '130.211.0.0/22', '209.85.152.0/22', '209.85.204.0/22'],
                'targetTags': [context.properties['infra_id'] + '-master']
            }
        },
        {
            'name': context.properties['infra_id'] + '-etcd',
            'type': 'compute.v1.firewall',
            'properties': {
                'network': context.properties['cluster_network'],
                'allowed': [
                    {
                        'IPProtocol': 'tcp',
                        'ports': ['2379', '10250']
                    }
                ],
                'sourceRanges': [context.properties['allowed_external_cidr']],
                'targetTags': [context.properties['infra_id'] + '-etcd']
            }
        }
    ]
    return resources
```

```

'type': 'compute.v1.firewall',
'properties': {
    'network': context.properties['cluster_network'],
    'allowed': [
        {
            'IPProtocol': 'tcp',
            'ports': ['2379-2380']
        },
        {
            'sourceTags': [context.properties['infra_id'] + '-master'],
            'targetTags': [context.properties['infra_id'] + '-master']
        }
    ],
    {
        'name': context.properties['infra_id'] + '-control-plane',
        'type': 'compute.v1.firewall',
        'properties': {
            'network': context.properties['cluster_network'],
            'allowed': [
                {
                    'IPProtocol': 'tcp',
                    'ports': ['10257']
                },
                {
                    'IPProtocol': 'tcp',
                    'ports': ['10259']
                },
                {
                    'IPProtocol': 'tcp',
                    'ports': ['22623']
                }
            ],
            'sourceTags': [
                context.properties['infra_id'] + '-master',
                context.properties['infra_id'] + '-worker'
            ],
            'targetTags': [context.properties['infra_id'] + '-master']
        }
    },
    {
        'name': context.properties['infra_id'] + '-internal-network',
        'type': 'compute.v1.firewall',
        'properties': {
            'network': context.properties['cluster_network'],
            'allowed': [
                {
                    'IPProtocol': 'icmp'
                },
                {
                    'IPProtocol': 'tcp',
                    'ports': ['22']
                }
            ],
            'sourceRanges': [context.properties['network_cidr']],
            'targetTags': [
                context.properties['infra_id'] + '-master',
                context.properties['infra_id'] + '-worker'
            ]
        }
    },
    {
        'name': context.properties['infra_id'] + '-internal-cluster',
        'type': 'compute.v1.firewall',
        'properties': {
            'network': context.properties['cluster_network'],
            'allowed': [
                {
                    'IPProtocol': 'udp',
                    'ports': ['4789', '6081']
                }
            ]
        }
    }
}

```

```

    },{
      'IPProtocol': 'udp',
      'ports': ['500', '4500']
    },{
      'IPProtocol': 'esp',
    },{
      'IPProtocol': 'tcp',
      'ports': ['9000-9999']
    },{
      'IPProtocol': 'udp',
      'ports': ['9000-9999']
    },{
      'IPProtocol': 'tcp',
      'ports': ['10250']
    },{
      'IPProtocol': 'tcp',
      'ports': ['30000-32767']
    },{
      'IPProtocol': 'udp',
      'ports': ['30000-32767']
    }],
    'sourceTags': [
      context.properties['infra_id'] + '-master',
      context.properties['infra_id'] + '-worker'
    ],
    'targetTags': [
      context.properties['infra_id'] + '-master',
      context.properties['infra_id'] + '-worker'
    ]
  }
}

return {'resources': resources}

```

7.12.12. Creating IAM roles in GCP

You must create IAM roles in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure

1. Copy the template from the **Deployment Manager template for IAM roles** section of this topic and save it as **03_iam.py** on your computer. This template describes the IAM roles that your cluster requires.
2. Create a **03_iam.yaml** resource definition file:

```
$ cat <<EOF >03_iam.yaml
imports:
- path: 03_iam.py
resources:
- name: cluster-iam
  type: 03_iam.py
  properties:
    infra_id: '${INFRA_ID}' 1
EOF
```

1 `infra_id` is the `INFRA_ID` infrastructure name from the extraction step.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-iam --config 03_iam.yaml
```

4. Export the variable for the master service account:

```
$ export MASTER_SERVICE_ACCOUNT=`gcloud iam service-accounts list --filter
'email~^${INFRA_ID}-m@${PROJECT_NAME}.' --format json | jq -r '[0].email'`
```

5. Export the variable for the worker service account:

```
$ export WORKER_SERVICE_ACCOUNT=`gcloud iam service-accounts list --filter
'email~^${INFRA_ID}-w@${PROJECT_NAME}.' --format json | jq -r '[0].email'`
```

6. Export the variable for the subnet that hosts the compute machines:

```
$ export COMPUTE_SUBNET=`gcloud compute networks subnets describe ${INFRA_ID}-worker-subnet --region=${REGION} --format json | jq -r .selfLink`
```

7. The templates do not create the policy bindings due to limitations of Deployment Manager, so you must create them manually:

```
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.instanceAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.securityAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/iam.serviceAccountUser"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/storage.admin"
```

```
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member "serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role "roles/compute.viewer"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member "serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role "roles/storage.admin"
```

8. Create a service account key and store it locally for later use:

```
$ gcloud iam service-accounts keys create service-account-key.json --iam-account=${MASTER_SERVICE_ACCOUNT}
```

7.12.12.1. Deployment Manager template for IAM roles

You can use the following Deployment Manager template to deploy the IAM roles that you need for your OpenShift Container Platform cluster:

Example 7.24. 03_iam.py Deployment Manager template

```
def GenerateConfig(context):
    resources = [
        {
            'name': context.properties['infra_id'] + '-master-node-sa',
            'type': 'iam.v1.serviceAccount',
            'properties': {
                'accountId': context.properties['infra_id'] + '-m',
                'displayName': context.properties['infra_id'] + '-master-node'
            }
        },
        {
            'name': context.properties['infra_id'] + '-worker-node-sa',
            'type': 'iam.v1.serviceAccount',
            'properties': {
                'accountId': context.properties['infra_id'] + '-w',
                'displayName': context.properties['infra_id'] + '-worker-node'
            }
        }
    ]
    return {'resources': resources}
```

7.12.13. Creating the RHCOS cluster image for the GCP infrastructure

You must use a valid Red Hat Enterprise Linux CoreOS (RHCOS) image for Google Cloud Platform (GCP) for your OpenShift Container Platform nodes.

Procedure

1. Obtain the RHCOS image from the [RHCOS image mirror](#) page.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

The file name contains the OpenShift Container Platform version number in the format **rhcoss-<version>-<arch>-gcp.<arch>.tar.gz**.

2. Create the Google storage bucket:

```
$ gsutil mb gs://<bucket_name>
```

3. Upload the RHCOS image to the Google storage bucket:

```
$ gsutil cp <downloaded_image_file_path>/rhcoss-<version>-x86_64-gcp.x86_64.tar.gz  
gs://<bucket_name>
```

4. Export the uploaded RHCOS image location as a variable:

```
$ export IMAGE_SOURCE='gs://<bucket_name>/rhcoss-<version>-x86_64-  
gcp.x86_64.tar.gz'
```

5. Create the cluster image:

```
$ gcloud compute images create "${INFRA_ID}-rhcoss-image" \  
--source-uri="${IMAGE_SOURCE}"
```

7.12.14. Creating the bootstrap machine in GCP

You must create the bootstrap machine in Google Cloud Platform (GCP) to use during OpenShift Container Platform cluster initialization. One way to create this machine is to modify the provided Deployment Manager template.

**NOTE**

If you do not use the provided Deployment Manager template to create your bootstrap machine, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.

- Create control plane and compute roles.
- Ensure pyOpenSSL is installed.

Procedure

1. Copy the template from the **Deployment Manager template for the bootstrap machine** section of this topic and save it as **04_bootstrap.py** on your computer. This template describes the bootstrap machine that your cluster requires.
2. Export the location of the Red Hat Enterprise Linux CoreOS (RHCOS) image that the installation program requires:

```
$ export CLUSTER_IMAGE=`gcloud compute images describe ${INFRA_ID}-rhcos-image --format json | jq -r .selfLink`
```

3. Create a bucket and upload the **bootstrap.ign** file:

```
$ gsutil mb gs://${INFRA_ID}-bootstrap-ignition
$ gsutil cp <installation_directory>/bootstrap.ign gs://${INFRA_ID}-bootstrap-ignition/
```

4. Create a signed URL for the bootstrap instance to use to access the Ignition config. Export the URL from the output as a variable:

```
$ export BOOTSTRAP_IGN=`gsutil signurl -d 1h service-account-key.json gs://${INFRA_ID}-bootstrap-ignition/bootstrap.ign | grep '^gs:' | awk '{print $5}'`
```

5. Create a **04_bootstrap.yaml** resource definition file:

```
$ cat <<EOF >04_bootstrap.yaml
imports:
- path: 04_bootstrap.py

resources:
- name: cluster-bootstrap
  type: 04_bootstrap.py
  properties:
    infra_id: '${INFRA_ID}' 1
    region: '${REGION}' 2
    zone: '${ZONE_0}' 3

    cluster_network: '${CLUSTER_NETWORK}' 4
    control_subnet: '${CONTROL_SUBNET}' 5
    image: '${CLUSTER_IMAGE}' 6
    machine_type: 'n1-standard-4' 7
    root_volume_size: '128' 8

    bootstrap_ign: '${BOOTSTRAP_IGN}' 9
EOF
```

1 **infra_id** is the **INFRA_ID** infrastructure name from the extraction step.

2 **region** is the region to deploy the cluster into, for example **us-central1**.

- 3 **zone** is the zone to deploy the bootstrap instance into, for example **us-central1-b**.
- 4 **cluster_network** is the **selfLink** URL to the cluster network.
- 5 **control_subnet** is the **selfLink** URL to the control subnet.
- 6 **image** is the **selfLink** URL to the RHCOS image.
- 7 **machine_type** is the machine type of the instance, for example **n1-standard-4**.
- 8 **root_volume_size** is the boot disk size for the bootstrap machine.
- 9 **bootstrap_ign** is the URL output when creating a signed URL.

6. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-bootstrap --config
04_bootstrap.yaml
```

7. The templates do not manage load balancer membership due to limitations of Deployment Manager, so you must add the bootstrap machine manually.

a. Add the bootstrap instance to the internal load balancer instance group:

```
$ gcloud compute instance-groups unmanaged add-instances \
${INFRA_ID}-bootstrap-instance-group --zone=${ZONE_0} --instances=${INFRA_ID}-
bootstrap
```

b. Add the bootstrap instance group to the internal load balancer backend service:

```
$ gcloud compute backend-services add-backend \
${INFRA_ID}-api-internal-backend-service --region=${REGION} --instance-
group=${INFRA_ID}-bootstrap-instance-group --instance-group-zone=${ZONE_0}
```

7.12.14.1. Deployment Manager template for the bootstrap machine

You can use the following Deployment Manager template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster:

Example 7.25. 04_bootstrap.py Deployment Manager template

```
def GenerateConfig(context):

    resources = [
        'name': context.properties['infra_id'] + '-bootstrap-public-ip',
        'type': 'compute.v1.address',
        'properties': {
            'region': context.properties['region']
        }
    ],
    {
        'name': context.properties['infra_id'] + '-bootstrap',
        'type': 'compute.v1.instance',
        'properties': {
            'disks': [
                {
                    'boot': True,
                    'autoDelete': True,
                    'initializeParams': {
                        'diskSizeGb': 20
                    },
                    'sourceImage': context.properties['rhcos']
                }
            ]
        }
    }
]
```

```

        'autoDelete': True,
        'boot': True,
        'initializeParams': {
            'diskSizeGb': context.properties['root_volume_size'],
            'sourceImage': context.properties['image']
        }
    ],
    'machineType': 'zones/' + context.properties['zone'] + '/machineTypes/' +
context.properties['machine_type'],
    'metadata': {
        'items': [
            {
                'key': 'user-data',
                'value': '{"ignition":{"config":{"replace":{"source":"' + context.properties['bootstrap_ign'] +
+ '"}},"version":"3.1.0"}}'
            }
        ],
        'networkInterfaces': [
            {
                'subnetwork': context.properties['control_subnet'],
                'accessConfigs': [
                    {
                        'natIP': '$(ref.' + context.properties['infra_id'] + '-bootstrap-public-ip.address)'
                    }
                ],
                'tags': {
                    'items': [
                        context.properties['infra_id'] + '-master',
                        context.properties['infra_id'] + '-bootstrap'
                    ]
                },
                'zone': context.properties['zone']
            }
        ],
        'name': context.properties['infra_id'] + '-bootstrap-instance-group',
        'type': 'compute.v1.instanceGroup',
        'properties': {
            'namedPorts': [
                {
                    'name': 'ignition',
                    'port': 22623
                },
                {
                    'name': 'https',
                    'port': 6443
                }
            ],
            'network': context.properties['cluster_network'],
            'zone': context.properties['zone']
        }
    }
]

return {'resources': resources}

```

7.12.15. Creating the control plane machines in GCP

You must create the control plane machines in Google Cloud Platform (GCP) for your cluster to use. One way to create these machines is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.

Procedure

1. Copy the template from the **Deployment Manager template for control plane machines** section of this topic and save it as **05_control_plane.py** on your computer. This template describes the control plane machines that your cluster requires.
2. Export the following variable required by the resource definition:

```
$ export MASTER_IGNITION=`cat <installation_directory>/master.ign`
```

3. Create a **05_control_plane.yaml** resource definition file:

```
$ cat <<EOF >05_control_plane.yaml
imports:
- path: 05_control_plane.py

resources:
- name: cluster-control-plane
  type: 05_control_plane.py
  properties:
    infra_id: '${INFRA_ID}' 1
    zones: 2
    - '${ZONE_0}'
    - '${ZONE_1}'
    - '${ZONE_2}'

    control_subnet: '${CONTROL_SUBNET}' 3
    image: '${CLUSTER_IMAGE}' 4
    machine_type: 'n1-standard-4' 5
    root_volume_size: '128'
    service_account_email: '${MASTER_SERVICE_ACCOUNT}' 6

    ignition: '${MASTER_IGNITION}' 7
EOF
```

- **1** `infra_id` is the **INFRA_ID** infrastructure name from the extraction step.
- 2** `zones` are the zones to deploy the control plane instances into, for example **us-central1-a**, **us-central1-b**, and **us-central1-c**.
- 3** `control_subnet` is the **selfLink** URL to the control subnet.
- 4** `image` is the **selfLink** URL to the RHCOS image.
- 5** `machine_type` is the machine type of the instance, for example **n1-standard-4**.
- 6** `service_account_email` is the email address for the master service account that you created.
- 7** `ignition` is the contents of the **master.ign** file.

4. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-control-plane --config
05_control_plane.yaml
```

5. The templates do not manage load balancer membership due to limitations of Deployment Manager, so you must add the control plane machines manually.

- Run the following commands to add the control plane machines to the appropriate instance groups:

```
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-
${ZONE_0}-instance-group --zone=${ZONE_0} --instances=${INFRA_ID}-master-0
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-
${ZONE_1}-instance-group --zone=${ZONE_1} --instances=${INFRA_ID}-master-1
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-
${ZONE_2}-instance-group --zone=${ZONE_2} --instances=${INFRA_ID}-master-2
```

- For an external cluster, you must also run the following commands to add the control plane machines to the target pools:

```
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances-
zone="${ZONE_0}" --instances=${INFRA_ID}-master-0
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances-
zone="${ZONE_1}" --instances=${INFRA_ID}-master-1
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances-
zone="${ZONE_2}" --instances=${INFRA_ID}-master-2
```

7.12.15.1. Deployment Manager template for control plane machines

You can use the following Deployment Manager template to deploy the control plane machines that you need for your OpenShift Container Platform cluster:

Example 7.26. 05_control_plane.py Deployment Manager template

```
def GenerateConfig(context):
```

```

resources = [
    {
        'name': context.properties['infra_id'] + '-master-0',
        'type': 'compute.v1.instance',
        'properties': {
            'disks': [
                {
                    'autoDelete': True,
                    'boot': True,
                    'initializeParams': {
                        'diskSizeGb': context.properties['root_volume_size'],
                        'diskType': 'zones/' + context.properties['zones'][0] + '/diskTypes/pd-ssd',
                        'sourceImage': context.properties['image']
                    }
                }
            ],
            'machineType': 'zones/' + context.properties['zones'][0] + '/machineTypes/' +
context.properties['machine_type'],
            'metadata': {
                'items': [
                    {
                        'key': 'user-data',
                        'value': context.properties['ignition']
                    }
                ],
                'networkInterfaces': [
                    {
                        'subnetwork': context.properties['control_subnet']
                    }
                ],
                'serviceAccounts': [
                    {
                        'email': context.properties['service_account_email'],
                        'scopes': ['https://www.googleapis.com/auth/cloud-platform']
                    }
                ],
                'tags': {
                    'items': [
                        context.properties['infra_id'] + '-master',
                    ]
                },
                'zone': context.properties['zones'][0]
            }
        },
        {
            'name': context.properties['infra_id'] + '-master-1',
            'type': 'compute.v1.instance',
            'properties': {
                'disks': [
                    {
                        'autoDelete': True,
                        'boot': True,
                        'initializeParams': {
                            'diskSizeGb': context.properties['root_volume_size'],
                            'diskType': 'zones/' + context.properties['zones'][1] + '/diskTypes/pd-ssd',
                            'sourceImage': context.properties['image']
                        }
                    }
                ],
                'machineType': 'zones/' + context.properties['zones'][1] + '/machineTypes/' +
context.properties['machine_type'],
                'metadata': {
                    'items': [
                        {
                            'key': 'user-data',
                            'value': context.properties['ignition']
                        }
                    ]
                },
            }
        }
    }
]

```

```

    'networkInterfaces': [
        'subnetwork': context.properties['control_subnet']
    ],
    'serviceAccounts': [
        'email': context.properties['service_account_email'],
        'scopes': ['https://www.googleapis.com/auth/cloud-platform']
    ],
    'tags': {
        'items': [
            context.properties['infra_id'] + '-master',
        ]
    },
    'zone': context.properties['zones'][1]
}
},
{
    'name': context.properties['infra_id'] + '-master-2',
    'type': 'compute.v1.instance',
    'properties': {
        'disks': [
            {
                'autoDelete': True,
                'boot': True,
                'initializeParams': {
                    'diskSizeGb': context.properties['root_volume_size'],
                    'diskType': 'zones/' + context.properties['zones'][2] + '/diskTypes/pd-ssd',
                    'sourceImage': context.properties['image']
                }
            },
            {
                'machineType': 'zones/' + context.properties['zones'][2] + '/machineTypes/' +
context.properties['machine_type'],
                'metadata': {
                    'items': [
                        {
                            'key': 'user-data',
                            'value': context.properties['ignition']
                        }
                    ]
                },
                'networkInterfaces': [
                    'subnetwork': context.properties['control_subnet']
                ],
                'serviceAccounts': [
                    'email': context.properties['service_account_email'],
                    'scopes': ['https://www.googleapis.com/auth/cloud-platform']
                ],
                'tags': {
                    'items': [
                        context.properties['infra_id'] + '-master',
                    ]
                },
                'zone': context.properties['zones'][2]
            }
        ]
    }
}

return {'resources': resources}

```

7.12.16. Wait for bootstrap completion and remove bootstrap resources in GCP

After you create all of the required infrastructure in Google Cloud Platform (GCP), wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

Procedure

1. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install wait-for bootstrap-complete --dir=<installation_directory> \ ①
--log-level info ②
```

- ① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.
- ② To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

If the command exits without a **FATAL** warning, your production control plane has initialized.

2. Delete the bootstrap resources:

```
$ gcloud compute backend-services remove-backend ${INFRA_ID}-api-internal-backend-
service --region=${REGION} --instance-group=${INFRA_ID}-bootstrap-instance-group --
instance-group-zone=${ZONE_0}
$ gsutil rm gs://${INFRA_ID}-bootstrap-ignition/bootstrap.ign
$ gsutil rb gs://${INFRA_ID}-bootstrap-ignition
$ gcloud deployment-manager deployments delete ${INFRA_ID}-bootstrap
```

7.12.17. Creating additional worker machines in GCP

You can create worker machines in Google Cloud Platform (GCP) for your cluster to use by launching individual instances discretely or by automated processes outside the cluster, such as auto scaling groups. You can also take advantage of the built-in cluster scaling mechanisms and the machine API in OpenShift Container Platform.

In this example, you manually launch one instance by using the Deployment Manager template. Additional instances can be launched by including additional resources of type **06_worker.py** in the file.

NOTE

If you do not use the provided Deployment Manager template to create your worker machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

Procedure

1. Copy the template from the **Deployment Manager template for worker machines** section of this topic and save it as **06_worker.py** on your computer. This template describes the worker machines that your cluster requires.
2. Export the variables that the resource definition uses.

- a. Export the subnet that hosts the compute machines:

```
$ export COMPUTE_SUBNET=`gcloud compute networks subnets describe ${INFRA_ID}-worker-subnet --region=${REGION} --format json | jq -r .selfLink`
```

- b. Export the email address for your service account:

```
$ export WORKER_SERVICE_ACCOUNT=`gcloud iam service-accounts list --filter "email~^${INFRA_ID}-w@${PROJECT_NAME}." --format json | jq -r '[0].email'`
```

- c. Export the location of the compute machine Ignition config file:

```
$ export WORKER_IGNITION=`cat <installation_directory>/worker.ign`
```

3. Create a **06_worker.yaml** resource definition file:

```
$ cat <<EOF >06_worker.yaml
imports:
- path: 06_worker.py

resources:
- name: 'worker-0' 1
  type: 06_worker.py
properties:
```

```

infra_id: '${INFRA_ID}' 2
zone: '${ZONE_0}' 3
compute_subnet: '${COMPUTE_SUBNET}' 4
image: '${CLUSTER_IMAGE}' 5
machine_type: 'n1-standard-4' 6
root_volume_size: '128'
service_account_email: '${WORKER_SERVICE_ACCOUNT}' 7
ignition: '${WORKER_IGNITION}' 8
- name: 'worker-1'
  type: 06_worker.py
  properties:
    infra_id: '${INFRA_ID}' 9
    zone: '${ZONE_1}' 10
    compute_subnet: '${COMPUTE_SUBNET}' 11
    image: '${CLUSTER_IMAGE}' 12
    machine_type: 'n1-standard-4' 13
    root_volume_size: '128'
    service_account_email: '${WORKER_SERVICE_ACCOUNT}' 14
    ignition: '${WORKER_IGNITION}' 15
EOF

```

- 1** **name** is the name of the worker machine, for example **worker-0**.
- 2** **9** **infra_id** is the **INFRA_ID** infrastructure name from the extraction step.
- 3** **10** **zone** is the zone to deploy the worker machine into, for example **us-central1-a**.
- 4** **11** **compute_subnet** is the **selfLink** URL to the compute subnet.
- 5** **12** **image** is the **selfLink** URL to the RHCOS image.
- 6** **13** **machine_type** is the machine type of the instance, for example **n1-standard-4**.
- 7** **14** **service_account_email** is the email address for the worker service account that you created.
- 8** **15** **ignition** is the contents of the **worker.ign** file.

4. Optional: If you want to launch additional instances, include additional resources of type **06_worker.py** in your **06_worker.yaml** resource definition file.
5. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-worker --config 06_worker.yaml
```

7.12.17.1. Deployment Manager template for worker machines

You can use the following Deployment Manager template to deploy the worker machines that you need for your OpenShift Container Platform cluster:

Example 7.27. 06_worker.py Deployment Manager template

```

def GenerateConfig(context):

    resources = [
        'name': context.properties['infra_id'] + '-' + context.env['name'],
        'type': 'compute.v1.instance',
        'properties': {
            'disks': [
                {
                    'autoDelete': True,
                    'boot': True,
                    'initializeParams': {
                        'diskSizeGb': context.properties['root_volume_size'],
                        'sourceImage': context.properties['image']
                    }
                }
            ],
            'machineType': 'zones/' + context.properties['zone'] + '/machineTypes/' +
context.properties['machine_type'],
            'metadata': {
                'items': [
                    {
                        'key': 'user-data',
                        'value': context.properties['ignition']
                    }
                ],
                'networkInterfaces': [
                    {
                        'subnetwork': context.properties['compute_subnet']
                    }
                ],
                'serviceAccounts': [
                    {
                        'email': context.properties['service_account_email'],
                        'scopes': ['https://www.googleapis.com/auth/cloud-platform']
                    }
                ],
                'tags': {
                    'items': [
                        context.properties['infra_id'] + '-worker',
                    ]
                },
                'zone': context.properties['zone']
            }
        }
    ]

    return {'resources': resources}

```

7.12.18. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

7.12.19. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding **disableAllDefaultSources: true** to the **OperatorHub** object:

```
$ oc patch OperatorHub cluster --type json \
-p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
```

TIP

Alternatively, you can use the web console to manage catalog sources. From the **Administration → Cluster Settings → Global Configuration → OperatorHub** page, click the **Sources** tab, where you can create, delete, disable, and enable individual sources.

7.12.20. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.22.1
master-1	Ready	master	63m	v1.22.1
master-2	Ready	master	64m	v1.22.1

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

- Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-8b2br	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
csr-8vnps	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
...			

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

- If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	
Pending			
csr-c571v	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	
Pending			
...			

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	73m	v1.22.1
master-1	Ready	master	73m	v1.22.1
master-2	Ready	master	74m	v1.22.1
worker-0	Ready	worker	11m	v1.22.1
worker-1	Ready	worker	11m	v1.22.1

NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

7.12.21. Optional: Adding the ingress DNS records

If you removed the DNS zone configuration when creating Kubernetes manifests and generating Ignition configs, you must manually create DNS records that point at the ingress load balancer. You can create either a wildcard ***.apps.{baseDomain}**, or specific records. You can use A, CNAME, and other records per your requirements.

Prerequisites

- Configure a GCP account.
- Remove the DNS Zone configuration when creating Kubernetes manifests and generating Ignition configs.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.
- Create the worker machines.

Procedure

1. Wait for the Ingress router to create a load balancer and populate the **EXTERNAL-IP** field:

```
$ oc -n openshift-ingress get service router-default
```

Example output

NAME	TYPE	CLUSTER-IP	EXTERNAL-IP	PORT(S)	AGE
router-default	LoadBalancer	172.30.18.154	35.233.157.184 80:32288/TCP,443:31215/TCP	98	

2. Add the A record to your zones:

- To use A records:

- i. Export the variable for the router IP address:

```
$ export ROUTER_IP=`oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}'`
```

- ii. Add the A record to the private zones:

```
$ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone
$ gcloud dns record-sets transaction add ${ROUTER_IP} --name
\*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone
${INFRA_ID}-private-zone
$ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone
```

- iii. For an external cluster, also add the A record to the public zones:

```
$ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction add ${ROUTER_IP} --name
\*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone
${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction execute --zone
${BASE_DOMAIN_ZONE_NAME}
```

- To add explicit domains instead of using a wildcard, create entries for each of the cluster's current routes:

```
$ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}
{"\n"}{end}{end}' routes
```

Example output

```
oauth-openshift.apps.your.cluster.domain.example.com
console-openshift-console.apps.your.cluster.domain.example.com
downloads-openshift-console.apps.your.cluster.domain.example.com
alertmanager-main-openshift-monitoring.apps.your.cluster.domain.example.com
grafana-openshift-monitoring.apps.your.cluster.domain.example.com
prometheus-k8s-openshift-monitoring.apps.your.cluster.domain.example.com
```

7.12.22. Completing a GCP installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Google Cloud Platform (GCP) user-provisioned infrastructure, you can monitor the cluster events until the cluster is ready.

Prerequisites

- Deploy the bootstrap machine for an OpenShift Container Platform cluster on user-provisioned GCP infrastructure.
- Install the **oc** CLI and log in.

Procedure

1. Complete the cluster installation:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete ①
```

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

2. Observe the running state of your cluster.

- a. Run the following command to view the current cluster version and status:

```
$ oc get clusterversion
```

Example output

NAME	VERSION	AVAILABLE	PROGRESSING	SINCE	STATUS
version		False	True	24m	Working towards 4.5.4: 99% complete

- b. Run the following command to view the Operators managed on the control plane by the Cluster Version Operator (CVO):

```
$ oc get clusteroperators
```

Example output

NAME	VERSION	AVAILABLE	PROGRESSING	DEGRADED
SINCE				
authentication	4.5.4	True	False	False 7m56s
cloud-credential	4.5.4	True	False	False 31m
cluster-autoscaler	4.5.4	True	False	False 16m
console	4.5.4	True	False	False 10m
csi-snapshot-controller	4.5.4	True	False	False 16m
dns	4.5.4	True	False	False 22m
etcd	4.5.4	False	False	False 25s
image-registry	4.5.4	True	False	False 16m
ingress	4.5.4	True	False	False 16m
insights	4.5.4	True	False	False 17m
kube-apiserver	4.5.4	True	False	False 19m
kube-controller-manager	4.5.4	True	False	False 20m
kube-scheduler	4.5.4	True	False	False 20m
kube-storage-version-migrator	4.5.4	True	False	False 16m
machine-api	4.5.4	True	False	False 22m
machine-config	4.5.4	True	False	False 22m
marketplace	4.5.4	True	False	False 16m
monitoring	4.5.4	True	False	False 10m

node-tuning	4.5.4	True	False	False 23m
openshift-apiserver	4.5.4	True	False	False 17m
openshift-controller-manager	4.5.4	True	False	False 15m
openshift-samples	4.5.4	True	False	False 16m
operator-lifecycle-manager	4.5.4	True	False	False 22m
operator-lifecycle-manager-catalog	4.5.4	True	False	False 22m
operator-lifecycle-manager-packageserver	4.5.4	True	False	False 18m
service-ca	4.5.4	True	False	False 23m
service-catalog-apiserver	4.5.4	True	False	False 23m
service-catalog-controller-manager	4.5.4	True	False	False 23m
storage	4.5.4	True	False	False 17m

- c. Run the following command to view your cluster pods:

```
$ oc get pods --all-namespaces
```

Example output

NAMESPACE	READY	STATUS	RESTARTS	AGE	NAME
kube-system					etcd-member-ip-10-0-3-111.us-east-
2.compute.internal	1/1	Running	0	35m	etcd-member-ip-10-0-3-239.us-east-

controller-manager-operator-b78cr2lnm  1/1  Running  0   31m

```

When the current cluster version is **AVAILABLE**, the installation is complete.

7.12.23. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

7.12.24. Next steps

- [Customize your cluster](#).
- [Configure image streams](#) for the Cluster Samples Operator and the **must-gather** tool.
- Learn how to [use Operator Lifecycle Manager \(OLM\) on restricted networks](#).
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by [configuring additional trust stores](#).
- If necessary, you can [opt out of remote health reporting](#).

7.13. UNINSTALLING A CLUSTER ON GCP

You can remove a cluster that you deployed to Google Cloud Platform (GCP).

7.13.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

NOTE

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access. For example, some Google Cloud resources require [IAM permissions](#) in shared VPC host projects, or there might be unused [health checks that must be deleted](#).

Prerequisites

- Have a copy of the installation program that you used to deploy the cluster.
- Have the files that the installation program generated when you created your cluster.

Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

```
$ ./openshift-install destroy cluster \
--dir=<installation_directory> --log-level=info ① ②
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.
- 2 To view different details, specify **warn**, **debug**, or **error** instead of **info**.

NOTE

You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the **metadata.json** file in this directory to delete the cluster.

2. Optional: Delete the **<installation_directory>** directory and the OpenShift Container Platform installation program.

CHAPTER 8. INSTALLING ON BARE METAL

8.1. PREPARING FOR BARE METAL CLUSTER INSTALLATION

8.1.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You have read the documentation on [selecting a cluster installation method and preparing it for users](#).

8.1.2. Choosing a method to install OpenShift Container Platform on bare metal

You can install OpenShift Container Platform on installer-provisioned or user-provisioned infrastructure. The default installation type uses installer-provisioned infrastructure, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provision. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See [Installation process](#) for more information about installer-provisioned and user-provisioned installation processes.

8.1.2.1. Installing a cluster on installer-provisioned infrastructure

You can install a cluster on bare metal infrastructure that is provisioned by the OpenShift Container Platform installation program, by using the following method:

- **Installing an installer-provisioned cluster on bare metal** You can install OpenShift Container Platform on bare metal by using installer provisioning.

8.1.2.2. Installing a cluster on user-provisioned infrastructure

You can install a cluster on bare metal infrastructure that you provision, by using one of the following methods:

- **Installing a user-provisioned cluster on bare metal** You can install OpenShift Container Platform on bare metal infrastructure that you provision. For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.
- **Installing a user-provisioned bare metal cluster with network customizations** You can install a bare metal cluster on user-provisioned infrastructure with network-customizations. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations. Most of the network customizations must be applied at the installation stage.
- **Installing a user-provisioned bare metal cluster on a restricted network** You can install a user-provisioned bare metal cluster on a restricted or disconnected network by using a mirror registry. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

8.2. INSTALLING A USER-PROVISIONED CLUSTER ON BARE METAL

In OpenShift Container Platform 4.9, you can install a cluster on bare metal infrastructure that you provision.

IMPORTANT

While you might be able to follow this procedure to deploy a cluster on virtualized or cloud environments, you must be aware of additional considerations for non-bare metal platforms. Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you attempt to install an OpenShift Container Platform cluster in such an environment.

8.2.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

8.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

Additional resources

- See [Installing a user-provisioned bare metal cluster on a restricted network](#) for more information about performing a restricted network installation on bare metal infrastructure that you provision.

8.2.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

8.2.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

Table 8.1. Minimum required hosts

Hosts	Description
One temporary bootstrap machine	The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.
Three control plane machines	The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.
At least two compute machines, which are also known as worker machines.	The workloads requested by OpenShift Container Platform users run on the compute machines.

NOTE

As an exception, you can run zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production. Running one compute machine is not supported.

IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 7.9, or RHEL 8.4.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

8.2.3.2. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

Machine	Operating System	CPU [1]	RAM	Storage	IOPS [2]
Bootstrap	RHCOS	4	16 GB	100 GB	300
Control plane	RHCOS	4	16 GB	100 GB	300
Compute	RHCOS, RHEL 7.9, or RHEL 8.4 [3]	2	8 GB	100 GB	300

1. One CPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = CPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

8.2.3.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

Additional resources

- See [Configuring a three-node cluster](#) for details about deploying three-node clusters in bare metal environments.
- See [Approving the certificate signing requests for your machines](#) for more information about approving cluster certificate signing requests after installation.

8.2.3.4. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The

Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.

NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

8.2.3.4.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

8.2.3.4.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 8.2. Ports used for all-machine to all-machine communications

Protocol	Port	Description
ICMP	N/A	Network reachability tests

Protocol	Port	Description
TCP	1936	Metrics
	9000-9999	Host level services, including the node exporter on ports 9100-9101 and the Cluster Version Operator on port 9099 .
	10250-10259	The default ports that Kubernetes reserves
	10256	openshift-sdn
UDP	4789	VXLAN and Geneve
	6081	VXLAN and Geneve
	9000-9999	Host level services, including the node exporter on ports 9100-9101 .
TCP/UDP	30000-32767	Kubernetes node port

Table 8.3. Ports used for all-machine to control plane communications

Protocol	Port	Description
TCP	6443	Kubernetes API

Table 8.4. Ports used for control plane machine to control plane machine communications

Protocol	Port	Description
TCP	2379-2380	etcd server and peer ports

NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for [Configuring chrony time service](#).

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

Additional resources

- [Configuring chrony time service](#)

8.2.3.5. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

NOTE

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the *DHCP recommendations for user-provisioned infrastructure* section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>. <cluster_name>. <base_domain>..`

Table 8.5. Required DNS records

Component	Record	Description
Kubernetes API	<code>api.<cluster_name>. <base_domain>.</code>	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.
	<code>api-int.<cluster_name>. <base_domain>.</code>	A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.

IMPORTANT

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.

Component	Record	Description
Routes	<code>*.apps.<cluster_name>. <base_domain>.</code>	A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <code>console-openshift-console.apps. <cluster_name>. <base_domain></code> is used as a wildcard route to the OpenShift Container Platform console.
Bootstrap machine	<code>bootstrap.<cluster_name>. <base_domain>.</code>	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.
Control plane machines	<code><master><n>. <cluster_name>. <base_domain>.</code>	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.
Compute machines	<code><worker><n>. <cluster_name>. <base_domain>.</code>	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

NOTE

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

TIP

You can use the `dig` command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

8.2.3.5.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

Example 8.1. Sample DNS zone database

```
$TTL 1W

- ① Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.
- ② Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.
- ③ Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

- ④ Provides name resolution for the bootstrap machine.
- ⑤ ⑥ ⑦ Provides name resolution for the control plane machines.
- ⑧ ⑨ Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

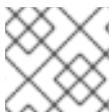

Example 8.2. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root (
    2019070700 ; serial
    3H ; refresh (3 hours)
    30M ; retry (30 minutes)
    2W ; expiry (2 weeks)
    1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. ①
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. ②
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. ③
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. ④
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. ⑤
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. ⑥
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. ⑦
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. ⑧
;
;EOF
```

- ① Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
- ② Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
- ③ Provides reverse DNS resolution for the bootstrap machine.
- ④ ⑤ ⑥ Provides reverse DNS resolution for the control plane machines.

7 8

Provides reverse DNS resolution for the compute machines.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

Additional resources

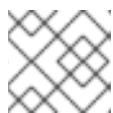

- [Validating DNS resolution for user-provisioned infrastructure](#)

8.2.3.6. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer:** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
 - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
 - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

NOTE

Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

Table 8.6. API load balancer

Port	Back-end machines (pool members)	Internal	External	Description
6443	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.	X	X	Kubernetes API server
22623	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.	X		Machine config server

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer.** Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 8.7. Application ingress load balancer

Port	Back-end machines (pool members)	Internal	External	Description
443	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTPS traffic
80	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTP traffic

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

8.2.3.6.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an [/etc/haproxy/haproxy.cfg](#) configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 8.3. Sample API and application ingress load balancer configuration

```

global
  log    127.0.0.1 local2
  pidfile /var/run/haproxy.pid
  maxconn 4000
  daemon
defaults
  mode      http
  log       global
  option    dontlognull
  option http-server-close
  option    redispatch

server worker1 worker1.ocp4.example.com:80 check inter 1s

```

- 1 In the example, the cluster name is **ocp4**.
- 2 Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
- 3 5 The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.
- 4 Port **22623** handles the machine config server traffic and points to the control plane machines.
- 6 Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
- 7 Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltpu** on the HAProxy node.

NOTE

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy_connect_any=1**.

8.2.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

Prerequisites

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
 - a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
 - b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

NOTE

If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

- c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the *Setting the cluster node hostnames through DHCP* section for details about hostname considerations.

NOTE

If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.

3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.
4. Setup the required DNS infrastructure for your cluster.
 - a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
 - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.
5. Validate your DNS configuration.
 - a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
 - b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.

See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.
6. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

Additional resources

- Requirements for a cluster with user-provisioned infrastructure
- Installing RHCOS and starting the OpenShift Container Platform bootstrap process
- Setting the cluster node hostnames through DHCP
- Advanced RHCOS installation configuration
- Networking requirements for user-provisioned infrastructure
- User-provisioned DNS requirements
- Validating DNS resolution for user-provisioned infrastructure
- Load balancing requirements for user-provisioned infrastructure

8.2.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
 - a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> ①
```

- ① Replace **<nameserver_ip>** with the IP address of the nameserver, **<cluster_name>** with your cluster name, and **<base_domain>** with your base domain name.

Example output

```
api.ocp4.example.com. 0 IN A 192.168.1.5
```

- b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

```
api-int.ocp4.example.com. 0 IN A 192.168.1.5
```

- c. Test an example ***.apps.<cluster_name>.<base_domain>** DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

```
random.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace **random** with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

- d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

- e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.
 - a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. ①  
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. ②
```

- ① Provides the record name for the Kubernetes internal API.
- ② Provides the record name for the Kubernetes API.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

- b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

- c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

Additional resources

- [User-provisioned DNS requirements](#)
- [Load balancing requirements for user-provisioned infrastructure](#)

8.2.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

Procedure

- If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N " -f <path>/<file_name> ①
```

- Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

- View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

- Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

- Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> ①
```

- 1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

Additional resources

- [Verifying node health](#)

8.2.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

- Access the [Infrastructure Provider](#) page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
- Select your infrastructure provider.
- Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

- Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

- From the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

8.2.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.9. Download and install the new version of **oc**.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

Procedure

- Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
- Select the appropriate version in the **Version** drop-down menu.
- Click **Download Now** next to the **OpenShift v4.9 Linux Client** entry and save the file.
- Unpack the archive:

```
$ tar xvzf <file>
```

- Place the **oc** binary in a directory that is on your **PATH**. To check your **PATH**, execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

Procedure

- Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
- Select the appropriate version in the **Version** drop-down menu.
- Click **Download Now** next to the **OpenShift v4.9 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.
To check your **PATH**, open the command prompt and execute the following command:

```
C:> path
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
C:> oc <command>
```

Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.9 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

8.2.9. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the `<installation_directory>`.

NOTE

You must name this configuration file **install-config.yaml**.

NOTE

For some platform types, you can alternatively run `./openshift-install create install-config --dir=<installation_directory>` to generate an **install-config.yaml** file. You can provide details about your cluster configuration at the prompts.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

8.2.9.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster's platform. When you create the **install-config.yaml** installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the **install-config.yaml** file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

IMPORTANT

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

8.2.9.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 8.8. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>. <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}} .	String of lowercase letters, hyphens (-), and periods (.), such as dev .
platform	The configuration for the specific platform upon which to perform the installation: aws , baremetal , azure , openstack , ovirt , vsphere , or {} . For additional information about platform , <platform> parameters, consult the table for your specific platform that follows.	Object

Parameter	Description	Values
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths": { "cloud.openshift.com": { "auth": "b3Blb=", "email": "you@example.com" }, "quay.io": { "auth": "b3Blb=", "email": "you@example.com" } } }</pre>

8.2.9.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 8.9. Network parameters

Parameter	Description	Values
networking	The configuration for the cluster network.	<p>Object</p>  <p>NOTE</p> <p>You cannot modify parameters specified by the networking object after installation.</p>
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	<p>The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>	<p>An array of objects. For example:</p> <pre> networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23 </pre>

Parameter	Description	Values
networking.clusterNetwork.cidr	Required if you use networking.clusterNetwork . An IP address block. An IPv4 network.	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a / 23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{(32 - 23)} - 2$) pod IP addresses.	A subnet prefix. The default value is 23 .
networking.serviceNetwork	The IP address block for services. The default value is 172.30.0.0/16 . The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.	An array with an IP address block in CIDR format. For example: <pre>networking: serviceNetwork: - 172.30.0.0/16</pre>
networking.machineNetwork	The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.	An array of objects. For example: <pre>networking: machineNetwork: - cidr: 10.0.0.0/16</pre>
networking.machineNetwork.cidr	Required if you use networking.machineNetwork . An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24 .	An IP network block in CIDR notation. For example, 10.0.0.0/16 .  NOTE Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

8.2.9.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 8.10. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .

Parameter	Description	Values
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.	Mint, Passthrough, Manual , or an empty string ("").

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the *Cloud Credential Operator* entry in the *Red Hat Operators* reference content.

Parameter	Description	Values
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	false or true
imageContentSources	Sources and repositories for the release-image content.	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	<p>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</p>	<p>Internal or External. The default value is External.</p> <p>Setting this field to Internal is not supported on non-cloud platforms.</p>

Parameter	Description	Values
sshKey	The SSH key or keys to authenticate access your cluster machines. 	One or more keys. For example: sshKey: <key1> <key2> <key3>

8.2.9.2. Sample `install-config.yaml` file for bare metal

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```
apiVersion: v1
baseDomain: example.com 1
compute: 2
- hyperthreading: Enabled 3
  name: worker
  replicas: 0 4
controlPlane: 5
  hyperthreading: Enabled 6
  name: master
  replicas: 3 7
metadata:
  name: test 8
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14 9
      hostPrefix: 23 10
  networkType: OpenShiftSDN
  serviceNetwork: 11
    - 172.30.0.0/16
platform:
  none: {} 12
  fips: false 13
pullSecret: '{"auths": ...}' 14
sshKey: 'ssh-ed25519 AAAA...' 15
```

1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

- 2 5 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute**
- 3 6 Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

IMPORTANT

If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

- 4 You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

- 7 The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.
- 8 The cluster name that you specified in your DNS records.
- 9 A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.
- 10 The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to **23**, then each node is assigned a /**23** subnet out of the given **cidr**, which allows for 510 ($2^{(32 - 23)} - 2$) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.
- 11 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.
- 12 You must set the platform to **none**. You cannot provide additional platform configuration variables for your platform.

WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as [installing a cluster on any platform](#), and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.
2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

13

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

14

The pull secret that you obtained from the [Red Hat OpenShift Cluster Manager](#) site. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

15

The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

Additional resources

- See [Load balancing requirements for user-provisioned infrastructure](#) for more information on the API and application ingress load balancing requirements.

8.2.9.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

NOTE

For bare metal installations, if you do not assign node IP addresses from the range that is specified in the **networking.machineNetwork[].cidr** field in the **install-config.yaml** file, you must include them in the **proxy.noProxy** field.

Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the **ec2.<region>.amazonaws.com**, **elasticloadbalancing.<region>.amazonaws.com**, and **s3.<region>.amazonaws.com** endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ①
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
  noProxy: example.com ③
  additionalTrustBundle: | ④
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
  ...
  ...
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpProxy** value.

- 2 A proxy URL to use for creating HTTPS connections outside the cluster. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use * to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace to hold the additional CA certificates. If you provide **additionalTrustBundle** and at least one proxy setting, the **Proxy** object is configured to reference the **user-ca-bundle** config map in the **trustedCA** field. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges the contents specified for the **trustedCA** parameter with the RHCOS trust bundle. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE

The installation program does not support the proxy **readinessEndpoints** field.

- 2 Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

8.2.9.4. Configuring a three-node cluster

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing **install-config.yaml** file.

Procedure

- Ensure that the number of compute replicas is set to 0 in your **install-config.yaml** file, as shown in the following **compute** stanza:

```
compute:
  - name: worker
```

```
platform: {}  
replicas: 0
```

NOTE

You must set the value of the **replicas** parameter for the compute machines to **0** when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.
- When you create the Kubernetes manifest files in the following procedure, ensure that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yaml** file is set to **true**. This enables your application workloads to run on the control plane nodes.
- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

8.2.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the **install-config.yaml** installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

Example output

```
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift
```

- 1 For **<installation_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

WARNING

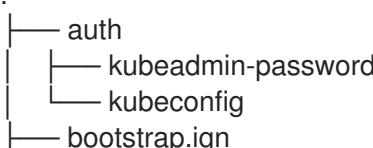

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

2. Check that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
 - a. Open the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file.
 - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
 - c. Save and exit the file.
3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory> ①
```

- 1 For **<installation_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation_directory>/auth** directory:

```

    └── master.ign
    └── metadata.json
    └── worker.ign

```

Additional resources

- See [Recovering from expired control plane certificates](#) for more information about recovering kubelet certificates.

8.2.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.

NOTE

The compute node deployment steps included in this installation document are RHCOS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

You can configure RHCOS during ISO and PXE installations by using the following methods:

- **Kernel arguments:** You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the **APPEND** parameter to pass the arguments to the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special **coreos.inst.*** arguments to direct the live installer, as well as standard installation boot arguments for turning standard kernel services on or off.
- **Ignition configs:** OpenShift Container Platform Ignition config files (***.ign**) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system after completing installation. This special Ignition config is consumed by the **coreos-installer** to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.
- **coreos-installer:** You can boot the live ISO installer to a shell prompt, which allows you to prepare the permanent system in a variety of ways before first boot. In particular, you can run the **coreos-installer** command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.

NOTE

As of OpenShift Container Platform 4.6, the RHCOS ISO and other installation artifacts provide support for installation on disks with 4K sectors.

8.2.11.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your **bootstrap.ign** Ignition config file:

```
$ sha512sum <installation_directory>/bootstrap.ign
```

Example output

```
a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf011  
6e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b  
installation_directory/bootstrap.ign
```

The digests are provided to the **coreos-installer** in a later step to validate the authenticity of the Ignition config files on the cluster nodes.

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
-
```

```
$ curl -k http://<HTTP_server>/bootstrap.ign ①
```

Example output

```
% Total % Received % Xferd Average Speed Time Time Time Current
          Dload Upload Total Spent Left Speed
0 0 0 0 0 0 0 --:-- --:-- --:-- 0{"ignition": "version": "3.2.0"}, "passwd": {"users": [{"name": "core", "sshAuthorizedKeys": ["ssh-rsa..."]}}
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

- Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

rhcoss-<version>-live.<architecture>.iso

- Use the ISO to start the RHCOS installation. Use one of the following installation options:
 - Burn the ISO image to a disk and boot it directly.
 - Use ISO redirection by using a lights-out management (LOM) interface.
- Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

NOTE

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the **coreos-installer** command as outlined in the following steps, instead of adding kernel arguments.

- Run the **coreos-installer** command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device>
--ignition-hash=SHA512-<digest> ①②
```

- You must run the **coreos-installer** command by using **sudo**, because the **core** user does not have the required root privileges to perform the installation.

- 2 The **--ignition-hash** option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node.

NOTE

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running **coreos-installer**.

The following example initializes a bootstrap node installation to the **/dev/sda** device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```
$ sudo coreos-installer install --ignition-
url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-
hash=SHA512-
a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf011
6e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.
10. Continue to create the other machines for your cluster.

IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running `ssh core@<node>.<cluster_name>`. **<base_domain>** as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

8.2.11.2. Installing RHCOS by using PXE or iPXE booting

You can use PXE or iPXE booting to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE or iPXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign ①
```

Example output

```
% Total % Received % Xferd Average Speed Time Time Time Current
          Dload Upload Total Spent Left Speed
0 0 0 0 0 0 0 --:--:-- --:--:-- --:--:-- 0{"ignition":
{"version":"3.2.0"}, "passwd": {"users": [{"name": "core", "sshAuthorizedKeys": ["ssh-rsa..."]}}]}
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Obtain the RHCOS **kernel**, **initramfs** and **rootfs** files from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate **kernel**, **initramfs**, and **rootfs** artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel: rhcos-<version>-live-kernel-<architecture>**
- **initramfs: rhcos-<version>-live-initramfs.<architecture>.img**
- **rootfs: rhcos-<version>-live-rootfs.<architecture>.img**

4. Upload the **rootfs**, **kernel**, and **initramfs** files to your HTTP server.

IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.
6. Configure PXE or iPXE installation for the RHCOS images and begin the installation. Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

- For PXE:

```
DEFAULT pxeboot
TIMEOUT 20
PROMPT 0
LABEL pxeboot
KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> ①
APPEND initrd=http://<HTTP_server>/rhcos-<version>-live-initramfs.
<architecture>.img coreos.live.rootfs_url=http://<HTTP_server>/rhcos-<version>-live-
rootfs.<architecture>.img coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign ② ③
```

① Specify the location of the live **kernel** file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

② If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named **eno1**, set **ip=eno1:dhcp**.

- 3 Specify the locations of the RHCOS files that you uploaded to your HTTP server. The **initrd** parameter value is the location of the **initramfs** file, the **coreos.live.rootfs_url**

NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more **console=** arguments to the **APPEND** line. For example, add **console=tty0** **console=ttyS0** to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](#).

- For iPXE:

```
kernel http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> initrd=main  
coreos.live.rootfs_url=http://<HTTP_server>/rhcos-<version>-live-rootfs.  
<architecture>.img coreos.inst.install_dev=/dev/sda  
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign ① ②  
initrd --name main http://<HTTP_server>/rhcos-<version>-live-initramfs.  
<architecture>.img ③  
boot
```

- 1 Specify the locations of the RHCOS files that you uploaded to your HTTP server. The **kernel** parameter value is the location of the **kernel** file, the **initrd=main** argument is needed for booting on UEFI systems, the **coreos.live.rootfs_url** parameter value is the location of the **rootfs** file, and the **coreos.inst.ignition_url** parameter value is the location of the bootstrap Ignition config file.
- 2 If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named **eno1**, set **ip=eno1:dhcp**.
- 3 Specify the location of the **initramfs** file that you uploaded to your HTTP server.

NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more **console=** arguments to the **kernel** line. For example, add **console=tty0** **console=ttyS0** to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](#).

7. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.
9. Continue to create the machines for your cluster.

IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running **ssh core@<node>.<cluster_name>**.

<base_domain> as a user with access to the SSH private key that is paired to the public key that you specified in your **install_config.yaml** file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

8.2.11.3. Advanced RHCOS installation configuration

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:

- Passing kernel arguments to the live installer
- Running **coreos-installer** manually from the live system
- Embedding Ignition configs in an ISO

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

8.2.11.3.1. Using advanced networking options for PXE and ISO installations

Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:

- Pass special kernel parameters when you boot the live installer.
- Use a machine config to copy networking files to the installed system.

- Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

- See the "Advanced RHCOS installation reference" tables.
- Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

Procedure

- Boot the ISO installer.
- From the live system shell prompt, configure networking for the live system using available RHEL tools, such as **nmcli** or **nmtui**.
- Run the **coreos-installer** command to install the system, adding the **--copy-network** option to copy networking configuration. For example:

```
$ coreos-installer install --copy-network \
--ignition-url=http://host/worker.ign /dev/sda
```

IMPORTANT

The **--copy-network** option only copies networking configuration found under **/etc/NetworkManager/system-connections**. In particular, it does not copy the system hostname.

- Reboot into the installed system.

Additional resources

- See [Getting started with nmcli](#) and [Getting started with nmtui](#) in the RHEL 8 documentation for more information about the **nmcli** and **nmtui** tools.

8.2.11.3.2. Disk partitioning

The disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless the default partitioning configuration is overridden. During the RHCOS installation, the size of the root file system is increased to use the remaining available space on the target device.

There are two cases where you might want to override the default partitioning when installing RHCOS on an OpenShift Container Platform cluster node:

- Creating separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for mounting **/var** or a subdirectory of **/var**, such as **/var/lib/etcd**, on a separate partition, but not both.

IMPORTANT

Kubernetes supports only two file system partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- **Retaining existing partitions:** For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to **coreos-installer** that allow you to retain existing data partitions.

WARNING

The use of custom partitions could result in those partitions not being monitored by OpenShift Container Platform or alerted on. If you are overriding the default partitioning, see [Understanding OpenShift File System Monitoring \(eviction conditions\)](#) for more information about how OpenShift Container Platform monitors your host file systems.

8.2.11.3.2.1. Creating a separate `/var` partition

In general, you should use the default disk partitioning that is created during the RHCOS installation. However, there are cases where you might want to create a separate partition for a directory that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` directory or a subdirectory of `/var`. For example:

- **`/var/lib/containers`:** Holds container-related content that can grow as more images and containers are added to a system.
- **`/var/lib/etcd`:** Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **`/var`:** Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

The use of a separate partition for the `/var` directory or a subdirectory of `/var` also prevents data growth in the partitioned directory from filling up the root file system.

The following procedure sets up a separate `/var` partition by adding a machine config manifest that is wrapped into the Ignition config file for a node type during the preparation phase of an installation.

Procedure

1. On your installation host, change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ openshift-install create manifests --dir=<installation_directory>
```

2. Create a Butane config that configures the additional partition. For example, name the file **\$HOME/clusterconfig/98-var-partition.bu**, change the disk device name to the name of the storage device on the **worker** systems, and set the storage size as appropriate. This example places the **/var** directory on a separate partition:

```
variant: openshift
version: 4.9.0
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
storage:
  disks:
    - device: /dev/<device_name> ①
      partitions:
        - label: var
          start_mib: <partition_start_offset> ②
          size_mib: <partition_size> ③
      filesystems:
        - device: /dev/disk/by-partlabel/var
          path: /var
          format: xfs
          mount_options: [defaults, prjquota] ④
          with_mount_unit: true
```

- ① The storage device name of the disk that you want to partition.
- ② When adding a data partition to the boot disk, a minimum offset value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no offset value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
- ③ The size of the data partition in mebibytes.
- ④ The **prjquota** mount option must be enabled for filesystems used for container storage.

NOTE

When creating a separate **/var** partition, you cannot use different instance types for compute nodes, if the different instance types do not have the same device name.

3. Create a manifest from the Butane config and save it to the **clusterconfig/openshift** directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

4. Create the Ignition config files:

```
$ openshift-install create ignition-configs --dir=<installation_directory> ①
```

- For <installation_directory>, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory:

The files in the <installation_directory>/manifest and <installation_directory>/openshift directories are wrapped into the Ignition config files, including the file that contains the **98-var-partition** custom **MachineConfig** object.

Next steps

- You can apply the custom disk partitioning by referencing the Ignition config files during the RHCOS installations.

8.2.11.3.2.2. Retaining existing partitions

For an ISO installation, you can add options to the **coreos-installer** command that cause the installer to maintain one or more existing partitions. For a PXE installation, you can add **coreos.inst.*** options to the **APPEND** parameter to preserve partitions.

Saved partitions might be data partitions from an existing OpenShift Container Platform system. You can identify the disk partitions you want to keep either by partition label or by number.

NOTE

If you save existing partitions, and those partitions do not leave enough space for RHCOS, the installation will fail without damaging the saved partitions.

Retaining existing partitions during an ISO installation

This example preserves any partition in which the partition label begins with **data** (**data***):

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
--save-partlabel 'data*' /dev/sda
```

The following example illustrates running the **coreos-installer** in a way that preserves the sixth (6) partition on the disk:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
--save-partindex 6 /dev/sda
```

This example preserves partitions 5 and higher:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign
--save-partindex 5- /dev/sda
```

In the previous examples where partition saving is used, **coreos-installer** recreates the partition immediately.

Retaining existing partitions during a PXE installation

This **APPEND** option preserves any partition in which the partition label begins with 'data' ('data*'):

```
coreos.inst.save_partlabel=data*
```

This **APPEND** option preserves partitions 5 and higher:

```
coreos.inst.save_partindex=5-
```

This **APPEND** option preserves partition 6:

```
coreos.inst.save_partindex=6
```

8.2.11.3.3. Identifying Ignition configs

When doing an RHCOS manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

- **Permanent install Ignition config:** Every manual RHCOS installation needs to pass one of the Ignition config files generated by **openshift-installer**, such as **bootstrap.ign**, **master.ign** and **worker.ign**, to carry out the installation.

IMPORTANT

It is not recommended to modify these Ignition config files directly. You can update the manifest files that are wrapped into the Ignition config files, as outlined in examples in the preceding sections.

For PXE installations, you pass the Ignition configs on the **APPEND** line using the **coreos.inst.ignition_url=** option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the **coreos-installer** command line with the **--ignition-url=** option. In both cases, only HTTP and HTTPS protocols are supported.

- **Live install Ignition config:** This type must be created manually and should be avoided if possible, as it is not supported by Red Hat. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before and/or after the RHCOS system installs to disk. This method should only be used for performing tasks that must be done once and not applied again later, such as with advanced partitioning that cannot be done using a machine config.

For PXE or ISO boots, you can create the Ignition config and **APPEND** the **ignition.config.url=** option to identify the location of the Ignition config. You also need to append **ignition.firstboot** **ignition.platform.id=metal** or the **ignition.config.url** option will be ignored.

8.2.11.3.3.1. Embedding a live install Ignition config in the RHCOS ISO

You can embed a live install Ignition config directly in an RHCOS ISO image. When the ISO image is booted, the embedded config will be applied automatically.

Procedure

1. Download the **coreos-installer** binary from the following image mirror page: <https://mirror.openshift.com/pub/openshift-v4/clients/coreos-installer/latest/>.
2. Retrieve the RHCOS ISO image and the Ignition config file, and copy them into an accessible directory, such as **/mnt**:

```
# cp rhcos-<version>-live.x86_64.iso bootstrap.ign /mnt/
# chmod 644 /mnt/rhcos-<version>-live.x86_64.iso
```

3. Run the following command to embed the Ignition config into the ISO:

```
# ./coreos-installer iso ignition embed -i /mnt/bootstrap.ign \
/mnt/rhcos-<version>-live.x86_64.iso
```

You can now use that ISO to install RHCOS using the specified live install Ignition config.

IMPORTANT

Using **coreos-installer iso ignition embed** to embed a file generated by **openshift-installer**, such as **bootstrap.ign**, **master.ign** and **worker.ign**, is unsupported and not recommended.

4. To show the contents of the embedded Ignition config and direct it into a file, run:

```
# ./coreos-installer iso ignition show /mnt/rhcos-<version>-live.x86_64.iso > mybootstrap.ign
# diff -s bootstrap.ign mybootstrap.ign
```

Example output

```
Files bootstrap.ign and mybootstrap.ign are identical
```

5. To remove the Ignition config and return the ISO to its pristine state so you can reuse it, run:

```
# ./coreos-installer iso ignition remove /mnt/rhcos-<version>-live.x86_64.iso
```

You can now embed another Ignition config into the ISO or use the ISO in its pristine state.

8.2.11.3.4. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the **coreos-installer** command.

8.2.11.3.4.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

IMPORTANT

When adding networking arguments manually, you must also add the **rd.neednet=1** kernel argument to bring the network up in the initramfs.

The following table provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the **ip=**, **nameserver=**, and **bond=** kernel arguments.

NOTE

Ordering is important when adding the kernel arguments: **ip=**, **nameserver=**, and then **bond=**.

The networking options are passed to the **dracut** tool during system boot. For more information about the networking options supported by **dracut**, see the **dracut.cmdline** manual page.

Table 8.11. Networking and bonding options for ISO installations

Description	Examples
<p>To configure an IP address, either use DHCP (ip=dhcp) or set an individual static IP address (ip=<host_ip>). If setting a static IP, you must then identify the DNS server IP address (nameserver=<dns_ip>) on each node. This example sets:</p> <ul style="list-style-type: none"> • The node's IP address to 10.10.10.2 • The gateway address to 10.10.10.254 • The netmask to 255.255.255.0 • The hostname to core0.example.com • The DNS server address to 4.4.4.41 • The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically. 	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none nameserver=4.4.4.41</pre>

NOTE

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

Description	Examples
<p>Specify multiple network interfaces by specifying multiple ip= entries.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none</pre>
<p>Optional: You can configure routes to additional networks by setting an rd.route= value.</p> <p>If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.</p>	<p>To configure the default gateway:</p> <pre>ip=:10.10.10.254::</pre> <p>To configure the route for the additional network:</p> <pre>rd.route=20.20.20.0/24:20.20.20.254:enp2s0</pre>
<p>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the enp1s0 interface has a static networking configuration and DHCP is disabled for enp2s0, which is not used.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ip=:core0.example.com:enp2s0:none</pre>
<p>You can combine DHCP and static IP configurations on systems with multiple network interfaces.</p>	<pre>ip=enp1s0:dhcp ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none</pre>
<p>Optional: You can configure VLANs on individual interfaces by using the vlan= parameter.</p>	<p>To configure a VLAN on a network interface and use a static IP address:</p> <pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none vlan=enp2s0.100:enp2s0</pre> <p>To configure a VLAN on a network interface and to use DHCP:</p> <pre>ip=enp2s0.100:dhcp vlan=enp2s0.100:enp2s0</pre>
<p>You can provide multiple DNS servers by adding a nameserver= entry for each server.</p>	<pre>nameserver=1.1.1.1 nameserver=8.8.8.8</pre>

Description	Examples
<p>Optional: Bonding multiple network interfaces to a single interface is supported using the bond= option. In these two examples:</p> <ul style="list-style-type: none"> The syntax for configuring a bonded interface is: bond=name[:network_interfaces] [:options] <i>name</i> is the bonding device name (bond0), <i>network_interfaces</i> represents a comma-separated list of physical (ethernet) interfaces (em1,em2), and <i>options</i> is a comma-separated list of bonding options. Enter modinfo bonding to see available options. When you create a bonded interface using bond=, you must specify how the IP address is assigned and other information for the bonded interface. 	<p>To configure the bonded interface to use DHCP, set the bond's IP address to dhcp. For example:</p> <pre>bond=bond0:em1,em2:mode=active-backup ip=bond0:dhcp</pre> <p>To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:</p> <pre>bond=bond0:em1,em2:mode=active-backup ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:bond0:none</pre>
<p>Optional: You can configure VLANs on bonded interfaces by using the vlan= parameter.</p>	<p>To configure the bonded interface with a VLAN and to use DHCP:</p> <pre>ip=bond0.100:dhcp bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0</pre> <p>To configure the bonded interface with a VLAN and to use a static IP address:</p> <pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:bond0.100:none bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0</pre>

8.2.11.3.4.2. coreos-installer options for ISO installations

You can install RHCOS by running **coreos-installer install <options> <device>** at the command prompt, after booting into the RHCOS live environment from an ISO image.

The following table shows the subcommands, options, and arguments you can pass to the **coreos-installer** command.

Table 8.12. coreos-installer subcommands, command-line options, and arguments

coreos-installer install subcommand	
Subcommand	Description
\$ coreos-installer install <options> <device>	Embed an Ignition config in an ISO image.

coreos-installer install subcommand options	
Option	Description
-u, --image-url <url>	Specify the image URL manually.
-f, --image-file <path>	Specify a local image file manually. Used for debugging.
-i, --ignition-file <path>	Embed an Ignition config from a file.
-I, --ignition-url <URL>	Embed an Ignition config from a URL.
--ignition-hash <digest>	Digest type-value of the Ignition config.
-p, --platform <name>	Override the Ignition platform ID for the installed system.
--append-karg <arg>...	Append a default kernel argument to the installed system.
--delete-karg <arg>...	Delete a default kernel argument from the installed system.
-n, --copy-network	Copy the network configuration from the install environment. +
	 IMPORTANT The --copy-network option only copies networking configuration found under /etc/NetworkManager/system-connections . In particular, it does not copy the system hostname.
--network-dir <path>	For use with -n . Default is /etc/NetworkManager/system-connections/ .
--save-partlabel <lx>..	Save partitions with this label glob.
--save-partindex <id>...	Save partitions with this number or range.
--insecure	Skip signature verification.
--insecure-ignition	Allow Ignition URL without HTTPS or hash.

--architecture <name>	Target CPU architecture. Default is x86_64 .
--preserve-on-error	Do not clear partition table on error.
-h, --help	Print help information.

coreos-install install subcommand argument

<i>Argument</i>	<i>Description</i>
<device>	The destination device.

coreos-installer ISO Ignition subcommands

<i>Subcommand</i>	<i>Description</i>
\$ coreos-installer iso ignition embed <options> --ignition-file <file_path> <ISO_image>	Embed an Ignition config in an ISO image.
coreos-installer iso ignition show <options> <ISO_image>	Show the embedded Ignition config from an ISO image.
coreos-installer iso ignition remove <options> <ISO_image>	Remove the embedded Ignition config from an ISO image.

coreos-installer ISO Ignition subcommand options

<i>Option</i>	<i>Description</i>
-f, --force	Overwrite an existing Ignition config.
-i, --ignition-file <path>	The Ignition config to be used. Default is stdin .
-o, --output <path>	Write the ISO to a new output file.
-h, --help	Print help information.

coreos-installer PXE Ignition subcommands

<i>Subcommand</i>	<i>Description</i>
Note that not all of these options are accepted by all subcommands.	
coreos-installer pxe ignition wrap <options>	Wrap an Ignition config in an image.

coreos-installer pxe ignition unwrap <options> <image_name>	Show the wrapped Ignition config in an image.
coreos-installer PXE Ignition subcommand options	
<i>Option</i>	<i>Description</i>
Note that not all of these options are accepted by all subcommands.	
-i, --ignition-file <path>	The Ignition config to be used. Default is stdin .
-O, --output <path>	Write the ISO to a new output file.
-h, --help	Print help information.

8.2.11.3.4.3. coreos.inst boot options for ISO or PXE installations

You can automatically invoke **coreos-installer** options at boot time by passing **coreos.inst** boot arguments to the RHCOS live installer. These are provided in addition to the standard boot arguments.

- For ISO installations, the **coreos.inst** options can be added by interrupting the automatic boot at the bootloader menu. You can interrupt the automatic boot by pressing **TAB** while the **RHEL CoreOS (Live)** menu option is highlighted.
- For PXE or iPXE installations, the **coreos.inst** options must be added to the **APPEND** line before the RHCOS live installer is booted.

The following table shows the RHCOS live installer **coreos.inst** boot options for ISO and PXE installations.

Table 8.13. coreos.inst boot options

Argument	Description
coreos.inst.install_dev	Required. The block device on the system to install to. It is recommended to use the full path, such as /dev/sda , although sda is allowed.
coreos.inst.ignition_url	Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded. Only HTTP and HTTPS protocols are supported.
coreos.inst.save_partlabel	Optional: Comma-separated labels of partitions to preserve during the install. Glob-style wildcards are permitted. The specified partitions do not need to exist.

Argument	Description
coreos.inst.save_partindex	Optional: Comma-separated indexes of partitions to preserve during the install. Ranges m-n are permitted, and either m or n can be omitted. The specified partitions do not need to exist.
coreos.inst.insecure	Optional: Permits the OS image that is specified by coreos.inst.image_url to be unsigned.
coreos.inst.image_url	<p>Optional: Download and install the specified RHCOS image.</p> <ul style="list-style-type: none"> • This argument should not be used in production environments and is intended for debugging purposes only. • While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install. • If you are using coreos.inst.image_url, you must also use coreos.inst.insecure. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform. • Only HTTP and HTTPS protocols are supported.
coreos.inst.skip_reboot	Optional: The system will not reboot after installing. After the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only.
coreos.inst.platform_id	Optional: The Ignition platform ID of the platform the RHCOS image is being installed on. Default is metal . This option determines whether or not to request an Ignition config from the cloud provider, such as VMware. For example: coreos.inst.platform_id=vmware .
ignition.config.url	Optional: The URL of the Ignition config for the live boot. For example, this can be used to customize how coreos-installer is invoked, or to run code before or after the installation. This is different from coreos.inst.ignition_url , which is the Ignition config for the installed system.

8.2.11.4. Enabling multipathing with kernel arguments on RHCOS

RHCOS supports multipathing on the primary disk, allowing stronger resilience to hardware failure to achieve higher host availability.

You can enable multipathing at installation time for nodes that were provisioned in OpenShift Container Platform 4.8 or later. While post-installation support is available by activating multipathing via the machine config, enabling multipathing during installation is recommended.

In setups where any I/O to non-optimized paths results in I/O system errors, you must enable multipathing at installation time.

IMPORTANT

On IBM Z and LinuxONE, you can enable multipathing only if you configured your cluster for it during installation. For more information, see "Installing RHCOS and starting the OpenShift Container Platform bootstrap process" in *Installing a cluster with z/VM on IBM Z and LinuxONE*.

The following procedure enables multipath at installation time and appends kernel arguments to the **coreos-installer install** command so that the installed system itself will use multipath beginning from the first boot.

Prerequisites

- You have a running OpenShift Container Platform cluster that uses version 4.8 or later.
- You are logged in to the cluster as a user with administrative privileges.

Procedure

1. To enable multipath and start the **multipathd** daemon, run the following command:

```
$ mpathconf --enable && systemctl start multipathd.service
```

- Optional: If booting the PXE or ISO, you can instead enable multipath by adding **rd.multipath=default** from the kernel command line.

2. Append the kernel arguments by invoking the **coreos-installer** program:

- If there is only one multipath device connected to the machine, it should be available at path **/dev/mapper/mpatha**. For example:

```
$ coreos-installer install /dev/mapper/mpatha \ ①
--append-karg rd.multipath=default \
--append-karg root=/dev/disk/by-label/dm-mpath-root
```

① Indicates the path of the single multipathed device.

- If there are multiple multipath devices connected to the machine, or to be more explicit, instead of using **/dev/mapper/mpatha**, it is recommended to use the World Wide Name (WWN) symlink available in **/dev/disk/by-id**. For example:

```
$ coreos-installer install /dev/disk/by-id/wwn-<wwn_ID> \
--append-karg rd.multipath=default \
--append-karg root=/dev/disk/by-label/dm-mpath-root
```

- 1 Indicates the WWN ID of the target multipathed device. For example, **0xx194e957fcedb4841**.

This symlink can also be used as the **coreos.inst.install_dev** kernel argument when using special **coreos.inst.*** arguments to direct the live installer. For more information, see "Installing RHCOS and starting the OpenShift Container Platform bootstrap process".

- Check that the kernel arguments worked by going to one of the worker nodes and listing the kernel command line arguments (in **/proc/cmdline** on the host):

```
$ oc debug node/ip-10-0-141-105.ec2.internal
```

Example output

```
Starting pod/ip-10-0-141-105ec2internal-debug ...
To use host binaries, run `chroot /host`

sh-4.2# cat /host/proc/cmdline
...
rd.multipath=default root=/dev/disk/by-label/dm-mpath-root
...
sh-4.2# exit
```

You should see the added kernel arguments.

Additional resources

- See [Installing RHCOS and starting the OpenShift Container Platform bootstrap process](#) for more information on using special **coreos.inst.*** arguments to direct the live installer.

8.2.11.5. Updating the bootloader using bootupd

To update the bootloader by using **bootupd**, you must either install **bootupd** on RHCOS machines manually or provide a machine config with the enabled **systemd** unit. Unlike **grubby** or other bootloader tools, **bootupd** does not manage kernel space configuration such as passing kernel arguments.

After you have installed **bootupd**, you can manage it remotely from the OpenShift Container Platform cluster.

NOTE

It is recommended that you use **bootupd** only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

Manual install method

You can manually install **bootupd** by using the **bootctl** command-line tool.

1. Inspect the system status:

```
# bootupctl status
```

Example output

```
Component EFI
Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
Update: At latest version
```

2. RHCOS images created without **bootupd** installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

```
# bootupctl adopt-and-update
```

Example output

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

```
# bootupctl update
```

Example output

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

Machine config method

Another way to enable **bootupd** is by providing a machine config.

- Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

Example output

```
variant: rhcos
version: 1.1.0
systemd:
units:
- name: custom-bootupd-auto.service
  enabled: true
  contents: |
    [Unit]
    Description=Bootupd automatic update

    [Service]
    ExecStart=/usr/bin/bootupctl update
    RemainAfterExit=yes

    [Install]
    WantedBy=multi-user.target
```

8.2.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

```
$ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \ ①  
--log-level=info ②
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...  
INFO API v1.22.1 up  
INFO Waiting up to 30m0s for bootstrapping to complete...  
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

IMPORTANT

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

Additional resources

- See [Monitoring installation progress](#) for more information about monitoring the installation logs and retrieving diagnostic data if installation issues arise.

8.2.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- ① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

8.2.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.22.1
master-1	Ready	master	63m	v1.22.1
master-2	Ready	master	64m	v1.22.1

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

- Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-8b2br	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
csr-8vnps	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
...			

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

- If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approvers** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

- ① <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

NOTE

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	Pending
csr-c57lv	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	Pending
	...		

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

- ① <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs oc adm certificate approve
```

- After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	73m	v1.22.1

```
master-1 Ready master 73m v1.22.1
master-2 Ready master 74m v1.22.1
worker-0 Ready worker 11m v1.22.1
worker-1 Ready worker 11m v1.22.1
```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

8.2.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.9.0	True	False	False 19m
baremetal	4.9.0	True	False	False 37m
cloud-credential	4.9.0	True	False	False 40m
cluster-autoscaler	4.9.0	True	False	False 37m

openshift-controller-manager	4.9.0	True	False	False	30m
openshift-samples	4.9.0	True	False	False	32m
operator-lifecycle-manager	4.9.0	True	False	False	37m
operator-lifecycle-manager-catalog	4.9.0	True	False	False	37m
operator-lifecycle-manager-packageserver	4.9.0	True	False	False	32m
service-ca	4.9.0	True	False	False	38m
storage	4.9.0	True	False	False	37m

- Configure the Operators that are not available.

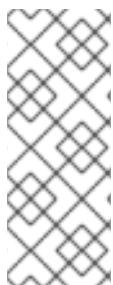

Additional resources

- See [Gathering logs from a failed installation](#) for details about gathering data in the event of a failed OpenShift Container Platform installation.
- See [Troubleshooting Operator issues](#) for steps to check Operator pod health across the cluster and gather Operator logs for diagnosis.

8.2.15.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the **managementState** from **Removed** to **Managed**.

NOTE

The Prometheus console provides an **ImageRegistryRemoved** alert, for example:

"Image Registry has been removed. **ImageStreamTags**, **BuildConfigs** and **DeploymentConfigs** which reference **ImageStreamTags** may not work as expected. Please configure storage and update the config to **Managed** state by editing configs.imageregistry.operator.openshift.io."

8.2.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

8.2.15.2.1. Configuring registry storage for bare metal and other manual installations

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster that uses manually-provisioned Red Hat Enterprise Linux CoreOS (RHCOS) nodes, such as bare metal.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Container Storage.

IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

NOTE

When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry
```

NOTE

If the storage type is **emptyDIR**, the replica number cannot be greater than **1**.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

Example output

```
storage:  
pvc:  
claim:
```

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

```
$ oc edit configs.imageregistry/cluster
```

Then, change the line

```
managementState: Removed
```

to

```
managementState: Managed
```

8.2.15.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage":{"emptyDir":{}}}}'
```

WARNING

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

8.2.15.2.3. Configuring block registry storage

To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

IMPORTANT

Block storage volumes are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

Procedure

- To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only one (1) replica:

```
$ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy":"Recreate", "replicas":1}}'
```

- Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.
- Edit the registry configuration so that it references the correct PVC.

8.2.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

- Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.9.0	True	False	False 19m
baremetal	4.9.0	True	False	False 37m
cloud-credential	4.9.0	True	False	False 40m
cluster-autoscaler	4.9.0	True	False	False 37m
config-operator	4.9.0	True	False	False 38m
console	4.9.0	True	False	False 26m
csi-snapshot-controller	4.9.0	True	False	False 37m
dns	4.9.0	True	False	False 37m
etcd	4.9.0	True	False	False 36m
image-registry	4.9.0	True	False	False 31m
ingress	4.9.0	True	False	False 30m
insights	4.9.0	True	False	False 31m
kube-apiserver	4.9.0	True	False	False 26m
kube-controller-manager	4.9.0	True	False	False 36m
kube-scheduler	4.9.0	True	False	False 36m
kube-storage-version-migrator	4.9.0	True	False	False 37m
machine-api	4.9.0	True	False	False 29m
machine approver	4.9.0	True	False	False 37m
machine-config	4.9.0	True	False	False 36m
marketplace	4.9.0	True	False	False 37m

monitoring	4.9.0	True	False	False	29m
network	4.9.0	True	False	False	38m
node-tuning	4.9.0	True	False	False	37m
openshift-apiserver	4.9.0	True	False	False	32m
openshift-controller-manager	4.9.0	True	False	False	30m
openshift-samples	4.9.0	True	False	False	32m
operator-lifecycle-manager	4.9.0	True	False	False	37m
operator-lifecycle-manager-catalog	4.9.0	True	False	False	37m
operator-lifecycle-manager-packageserver	4.9.0	True	False	False	32m
service-ca	4.9.0	True	False	False	38m
storage	4.9.0	True	False	False	37m

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete ①
```

- ① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.

- a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

Example output

NAMESPACE	NAME	READY	STATUS
RESTARTS AGE

- b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> ①
```

- ① Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.
See "Enabling multipathing with kernel arguments on RHCOS" in the *Post-installation machine configuration tasks* documentation for more information.

8.2.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

8.2.18. Next steps

- [Validating an installation.](#)
- [Customize your cluster.](#)
- If necessary, you can [opt out of remote health reporting](#) .
- [Set up your registry and configure registry storage](#) .

8.3. INSTALLING A USER-PROVISIONED BARE METAL CLUSTER WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform 4.9, you can install a cluster on bare metal infrastructure that you

provision with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations.

When you customize OpenShift Container Platform networking, you must set most of the network configuration parameters during installation. You can modify only **kubeProxy** network configuration parameters in a running cluster.

8.3.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- If you use a firewall and plan to use the Telemetry service, you [configured the firewall to allow the sites](#) that your cluster requires access to.

8.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

Additional resources

- See [Installing a user-provisioned bare metal cluster on a restricted network](#) for more information about performing a restricted network installation on bare metal infrastructure that you provision.

8.3.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

8.3.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

Table 8.14. Minimum required hosts

Hosts	Description
One temporary bootstrap machine	The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.
Three control plane machines	The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.
At least two compute machines, which are also known as worker machines.	The workloads requested by OpenShift Container Platform users run on the compute machines.

NOTE

As an exception, you can run zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production. Running one compute machine is not supported.

IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 7.9, or RHEL 8.4.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

8.3.3.2. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

Machine	Operating System	CPU [1]	RAM	Storage	IOPS [2]
Bootstrap	RHCOS	4	16 GB	100 GB	300
Control plane	RHCOS	4	16 GB	100 GB	300

Machine	Operating System	CPU [1]	RAM	Storage	IOPS [2]
Compute	RHCOS, RHEL 7.9, or RHEL 8.4 ^[3]	2	8 GB	100 GB	300

1. One CPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = CPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

8.3.3.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

Additional resources

- See [Configuring a three-node cluster](#) for details about deploying three-node clusters in bare metal environments.
- See [Approving the certificate signing requests for your machines](#) for more information about approving cluster certificate signing requests after installation.

8.3.3.4. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.

NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

8.3.3.4.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

8.3.3.4.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 8.15. Ports used for all-machine to all-machine communications

Protocol	Port	Description
ICMP	N/A	Network reachability tests
TCP	1936	Metrics

Protocol	Port	Description
	9000-9999	Host level services, including the node exporter on ports 9100-9101 and the Cluster Version Operator on port 9099 .
	10250-10259	The default ports that Kubernetes reserves
	10256	openshift-sdn
UDP	4789	VXLAN and Geneve
	6081	VXLAN and Geneve
	9000-9999	Host level services, including the node exporter on ports 9100-9101 .
TCP/UDP	30000-32767	Kubernetes node port

Table 8.16. Ports used for all-machine to control plane communications

Protocol	Port	Description
TCP	6443	Kubernetes API

Table 8.17. Ports used for control plane machine to control plane machine communications

Protocol	Port	Description
TCP	2379-2380	etcd server and peer ports

NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

Additional resources

- [Configuring chrony time service](#)

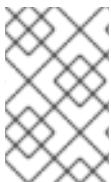

8.3.3.5. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

NOTE

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the *DHCP recommendations for user-provisioned infrastructure* section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>..`

Table 8.18. Required DNS records

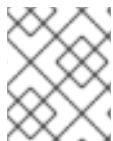

Component	Record	Description
Kubernetes API	<code>api.<cluster_name>.<base_domain>.</code>	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.
	<code>api-int.<cluster_name>.<base_domain>.</code>	A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.

IMPORTANT

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.

Component	Record	Description
Routes	<code>*.apps.<cluster_name>. <base_domain>.</code>	A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <code>console-openshift-console.apps.<cluster_name>. <base_domain></code> is used as a wildcard route to the OpenShift Container Platform console.
Bootstrap machine	<code>bootstrap.<cluster_name>. <base_domain>.</code>	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.
Control plane machines	<code><master><n>. <cluster_name>. <base_domain>.</code>	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.
Compute machines	<code><worker><n>. <cluster_name>. <base_domain>.</code>	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

NOTE

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

TIP

You can use the `dig` command to verify name and reverse name resolution. See the section on [Validating DNS resolution for user-provisioned infrastructure](#) for detailed validation steps.

8.3.3.5.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

Example 8.4. Sample DNS zone database

```
$TTL 1W
@ IN SOA ns1.example.com. root (

;
:EOF
```

- ① Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
- ② Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
- ③ Provides reverse DNS resolution for the bootstrap machine.
- ④ ⑤ ⑥ Provides reverse DNS resolution for the control plane machines.
- ⑦ ⑧ Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

- [Validating DNS resolution for user-provisioned infrastructure](#)

8.3.3.6. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer.** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
 - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
 - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**NOTE**

Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

Table 8.19. API load balancer

Port	Back-end machines (pool members)	Internal	External	Description
6443	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.	X	X	Kubernetes API server
22623	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.	X		Machine config server

NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer.** Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 8.20. Application ingress load balancer

Port	Back-end machines (pool members)	Internal	External	Description
443	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTPS traffic
80	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTP traffic

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

NOTE

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

8.3.3.6.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an [/etc/haproxy/haproxy.cfg](#) configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 8.6. Sample API and application ingress load balancer configuration

```

global
  log    127.0.0.1 local2
  pidfile /var/run/haproxy.pid
  maxconn 4000

  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup ③
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623 ④

```

```

bind *:22623
mode tcp
server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup 5
server master0 master0.ocp4.example.com:22623 check inter 1s
server master1 master1.ocp4.example.com:22623 check inter 1s
server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443 6
bind *:443
mode tcp
balance source
server worker0 worker0.ocp4.example.com:443 check inter 1s
server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80 7
bind *:80
mode tcp
balance source
server worker0 worker0.ocp4.example.com:80 check inter 1s
server worker1 worker1.ocp4.example.com:80 check inter 1s

```

- 1 In the example, the cluster name is **ocp4**.
- 2 Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
- 3 5 The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.
- 4 Port **22623** handles the machine config server traffic and points to the control plane machines.
- 6 Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
- 7 Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltpu** on the HAProxy node.

NOTE

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy_connect_any=1**.

8.3.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

Prerequisites

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
 - a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
 - b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

NOTE

If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

- c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the *Setting the cluster node hostnames through DHCP* section for details about hostname considerations.

NOTE

If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.

3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.
4. Setup the required DNS infrastructure for your cluster.
 - a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
 - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.
5. Validate your DNS configuration.
 - a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
 - b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.
6. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

Additional resources

- [Requirements for a cluster with user-provisioned infrastructure](#)
- [Installing RHCOS and starting the OpenShift Container Platform bootstrap process](#)
- [Setting the cluster node hostnames through DHCP](#)
- [Advanced RHCOS installation configuration](#)
- [Networking requirements for user-provisioned infrastructure](#)
- [User-provisioned DNS requirements](#)
- [Validating DNS resolution for user-provisioned infrastructure](#)
- [Load balancing requirements for user-provisioned infrastructure](#)

8.3.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
 - a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> ①
```

- 1 Replace **<nameserver_ip>** with the IP address of the nameserver, **<cluster_name>** with your cluster name, and **<base_domain>** with your base domain name.

Example output

```
api.ocp4.example.com. 0 IN A 192.168.1.5
```

- b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

```
api-int.ocp4.example.com. 0 IN A 192.168.1.5
```

- c. Test an example ***.apps.<cluster_name>.<base_domain>** DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

```
random.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace **random** with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

- d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

- e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.
 - a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. ①  
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. ②
```

- ① Provides the record name for the Kubernetes internal API.
- ② Provides the record name for the Kubernetes API.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

- b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

- c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

Additional resources

- [User-provisioned DNS requirements](#)
- [Load balancing requirements for user-provisioned infrastructure](#)

8.3.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

Procedure

- If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N " -f <path>/<file_name> ①
```

- Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

- View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

- Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

- Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> ①
```

- 1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

Additional resources

- [Verifying node health](#)

8.3.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

- Access the [Infrastructure Provider](#) page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
- Select your infrastructure provider.
- Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

- Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

- From the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

8.3.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.9. Download and install the new version of **oc**.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

Procedure

- Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
- Select the appropriate version in the **Version** drop-down menu.
- Click **Download Now** next to the **OpenShift v4.9 Linux Client** entry and save the file.
- Unpack the archive:

```
$ tar xvzf <file>
```

- Place the **oc** binary in a directory that is on your **PATH**.

To check your **PATH**, execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

Procedure

- Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
- Select the appropriate version in the **Version** drop-down menu.
- Click **Download Now** next to the **OpenShift v4.9 Windows Client** entry and save the file.
- Unzip the archive with a ZIP program.

5. Move the **oc** binary to a directory that is on your **PATH**.

To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.9 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.

To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

8.3.9. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation_directory>**.

NOTE

You must name this configuration file **install-config.yaml**.

NOTE

For some platform types, you can alternatively run `./openshift-install create install-config --dir=<installation_directory>` to generate an **install-config.yaml** file. You can provide details about your cluster configuration at the prompts.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

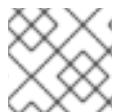

IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

8.3.9.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster's platform. When you create the **install-config.yaml** installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the **install-config.yaml** file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

IMPORTANT

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

8.3.9.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 8.21. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>. <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}} .	String of lowercase letters, hyphens (-), and periods (.), such as dev .
platform	The configuration for the specific platform upon which to perform the installation: aws , baremetal , azure , openstack , ovirt , vsphere , or {} . For additional information about platform , <platform> parameters, consult the table for your specific platform that follows.	Object

Parameter	Description	Values
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths": { "cloud.openshift.com": { "auth": "b3Blb=", "email": "you@example.com" }, "quay.io": { "auth": "b3Blb=", "email": "you@example.com" } } }</pre>

8.3.9.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 8.22. Network parameters

Parameter	Description	Values
networking	The configuration for the cluster network.	Object  NOTE You cannot modify parameters specified by the networking object after installation.
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23 . If you specify multiple IP address blocks, the blocks must not overlap.	An array of objects. For example: <pre>networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</pre>

Parameter	Description	Values
networking.clusterNetwork.cidr	Required if you use networking.clusterNetwork . An IP address block. An IPv4 network.	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{32 - 23} - 2$) pod IP addresses.	A subnet prefix. The default value is 23 .
networking.serviceNetwork	The IP address block for services. The default value is 172.30.0.0/16 . The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.	An array with an IP address block in CIDR format. For example: <pre>networking: serviceNetwork: - 172.30.0.0/16</pre>
networking.machineNetwork	The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.	An array of objects. For example: <pre>networking: machineNetwork: - cidr: 10.0.0.0/16</pre>
networking.machineNetwork.cidr	Required if you use networking.machineNetwork . An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24 .	An IP network block in CIDR notation. For example, 10.0.0.0/16 .  NOTE Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

8.3.9.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 8.23. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	 IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .

Parameter	Description	Values
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.	Mint, Passthrough, Manual , or an empty string ("").

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the *Cloud Credential Operator* entry in the *Red Hat Operators* reference content.

Parameter	Description	Values
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	false or true
imageContentSources	Sources and repositories for the release-image content.	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	<p>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</p>	<p>Internal or External. The default value is External.</p> <p>Setting this field to Internal is not supported on non-cloud platforms.</p>

Parameter	Description	Values
sshKey	The SSH key or keys to authenticate access your cluster machines. 	One or more keys. For example: sshKey: <key1> <key2> <key3>

8.3.9.2. Sample `install-config.yaml` file for bare metal

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```
apiVersion: v1
baseDomain: example.com 1
compute: 2
- hyperthreading: Enabled 3
  name: worker
  replicas: 0 4
controlPlane: 5
  hyperthreading: Enabled 6
  name: master
  replicas: 3 7
metadata:
  name: test 8
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14 9
      hostPrefix: 23 10
  networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
platform:
  none: {} 12
  tips: false 13
pullSecret: '{"auths": ...}' 14
sshKey: 'ssh-ed25519 AAAA...' 15
```

1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

- 2 5 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute**
- 3 6 Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

IMPORTANT

If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

- 4 You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

- 7 The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.
- 8 The cluster name that you specified in your DNS records.
- 9 A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.
- 10 The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to **23**, then each node is assigned a /**23** subnet out of the given **cidr**, which allows for 510 ($2^{(32 - 23)} - 2$) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.
- 11 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.
- 12 You must set the platform to **none**. You cannot provide additional platform configuration variables for your platform.

WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as [installing a cluster on any platform](#), and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.
2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

13

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

14

The pull secret that you obtained from the [Red Hat OpenShift Cluster Manager](#) site. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

15

The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

Additional resources

- See [Load balancing requirements for user-provisioned infrastructure](#) for more information on the API and application ingress load balancing requirements.

8.3.10. Network configuration phases

There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

Phase 1

You can customize the following network-related fields in the **install-config.yaml** file before you create the manifest files:

- **networking.networkType**
- **networking.clusterNetwork**
- **networking.serviceNetwork**
- **networking.machineNetwork**

For more information on these fields, refer to *Installation configuration parameters*.

NOTE

Set the **networking.machineNetwork** to match the CIDR that the preferred NIC resides in.

Phase 2

After creating the manifest files by running **openshift-install create manifests**, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.

You cannot override the values specified in phase 1 in the **install-config.yaml** file during phase 2. However, you can further customize the cluster network provider during phase 2.

8.3.11. Specifying advanced network configuration

You can use advanced network configuration for your cluster network provider to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

IMPORTANT

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

Prerequisites

- You have created the **install-config.yaml** file and completed any modifications to it.

Procedure

1. Change to the directory that contains the installation program and create the manifests:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

- ① **<installation_directory>** specifies the name of the directory that contains the **install-config.yaml** file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named **cluster-network-03-config.yml** in the <installation_directory>/manifests/ directory:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
```

3. Specify the advanced network configuration for your cluster in the **cluster-network-03-config.yml** file, such as in the following examples:

Specify a different VXLAN port for the OpenShift SDN network provider

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    openshiftSDNConfig:
      vxlanPort: 4800
```

Enable IPsec for the OVN-Kubernetes network provider

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    ovnKubernetesConfig:
      ipsecConfig: {}
```

4. Optional: Back up the **manifests/cluster-network-03-config.yml** file. The installation program consumes the **manifests**/ directory when you create the Ignition config files.

8.3.12. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named **cluster**. The CR specifies the fields for the **Network** API in the **operator.openshift.io** API group.

The CNO configuration inherits the following fields during cluster installation from the **Network** API in the **Network.config.openshift.io** API group and these fields cannot be changed:

clusterNetwork

IP address pools from which pod IP addresses are allocated.

serviceNetwork

IP address pool for services.

defaultNetwork.type

Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

8.3.12.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

Table 8.24. Cluster Network Operator configuration object

Field	Type	Description
metadata.name	string	The name of the CNO object. This name is always cluster .
spec.clusterNetwork	array	<p>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</p> <pre>spec: clusterNetwork: - cidr: 10.128.0.0/19 hostPrefix: 23 - cidr: 10.128.32.0/19 hostPrefix: 23</pre> <p>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</p>
spec.serviceNetwork	array	<p>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:</p> <pre>spec: serviceNetwork: - 172.30.0.0/14</pre> <p>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</p>
spec.defaultNetwork	object	Configures the Container Network Interface (CNI) cluster network provider for the cluster network.
spec.kubeProxyConfig	object	The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

defaultNetwork object configuration

The values for the **defaultNetwork** object are defined in the following table:

Table 8.25. defaultNetwork object

Field	Type	Description
type	string	<p>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</p>  <p>NOTE</p> <p>OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.</p>
openshiftSDNConfig	object	This object is only valid for the OpenShift SDN cluster network provider.
ovnKubernetesConfig	object	This object is only valid for the OVN-Kubernetes cluster network provider.

Configuration for the OpenShift SDN CNI cluster network provider

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

Table 8.26. openshiftSDNConfig object

Field	Type	Description
mode	string	<p>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy.</p> <p>The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</p>

Field	Type	Description
mtu	integer	<p>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.</p> <p>This value cannot be changed after cluster installation.</p>
vxlanPort	integer	<p>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.</p> <p>If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.</p> <p>On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</p>

Example OpenShift SDN configuration

```

defaultNetwork:
type: OpenShiftSDN
openshiftSDNConfig:
  mode: NetworkPolicy
  mtu: 1450
  vxlanPort: 4789

```

Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

Table 8.27. **ovnKubernetesConfig** object

Field	Type	Description
-------	------	-------------

Field	Type	Description
mtu	integer	<p>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.</p> <p>This value cannot be changed after cluster installation.</p>
genevePort	integer	The port to use for all Geneve packets. The default value is 6081 . This value cannot be changed after cluster installation.
ipsecConfig	object	Specify an empty object to enable IPsec encryption. This value cannot be changed after cluster installation.
policyAuditConfig	object	Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.

Table 8.28. **policyAuditConfig** object

Field	Type	Description
rateLimit	integer	The maximum number of messages to generate every second per node. The default value is 20 messages per second.
maxFileSize	integer	The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.

Field	Type	Description
destination	string	<p>One of the following additional audit log targets:</p> <p>libc The libc syslog() function of the journald process on the host.</p> <p>udp:<host>:<port> A syslog server. Replace <host>:<port> with the host and port of the syslog server.</p> <p>unix:<file> A Unix Domain Socket file specified by <file>.</p> <p>null Do not send the audit logs to any additional target.</p>
syslogFacility	string	The syslog facility, such as kern , as defined by RFC5424. The default value is local0 .

Example OVN-Kubernetes configuration

```
defaultNetwork:
type: OVNKubernetes
ovnKubernetesConfig:
  mtu: 1400
  genevePort: 6081
  ipsecConfig: {}
```

kubeProxyConfig object configuration

The values for the **kubeProxyConfig** object are defined in the following table:

Table 8.29. **kubeProxyConfig** object

Field	Type	Description
iptablesSyncPeriod	string	<p>The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</p> <div style="text-align: right;">  NOTE Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary. </div>

Field	Type	Description
<code>proxyArguments.iptables-min-sync-period</code>	array	<p>The minimum duration before refreshing <code>iptables</code> rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include <code>s</code>, <code>m</code>, and <code>h</code> and are described in the Go time package. The default value is:</p> <pre>kubeProxyConfig: proxyArguments: iptables-min-sync-period: - 0s</pre>

8.3.13. Creating the Ignition config files

Because you must manually start the cluster machines, you must generate the Ignition config files that the cluster needs to make its machines.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

- Obtain the Ignition config files:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory> ①
```

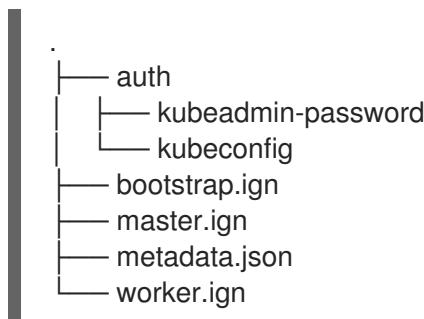

- ① For **<installation_directory>**, specify the directory name to store the files that the installation program creates.

IMPORTANT

If you created an **install-config.yaml** file, specify the directory that contains it. Otherwise, specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

The following files are generated in the directory:

8.3.14. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.

NOTE

The compute node deployment steps included in this installation document are RHCOS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

You can configure RHCOS during ISO and PXE installations by using the following methods:

- **Kernel arguments:** You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the **APPEND** parameter to pass the arguments to the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special **coreos.inst.*** arguments to direct the installer, as well as standard boot arguments for turning standard kernel services on or off.
- **Ignition configs:** OpenShift Container Platform Ignition config files (***.ign**) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system after completing installation. This special Ignition config is consumed by the **coreos-installer** to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.
- **coreos-installer:** You can boot the live ISO installer to a shell prompt, which allows you to prepare the permanent system in a variety of ways before first boot. In particular, you can run

the **coreos-installer** command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.

8.3.14.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your **bootstrap.ign** Ignition config file:

```
$ sha512sum <installation_directory>/bootstrap.ign
```

Example output

```
a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf011  
6e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b  
installation_directory/bootstrap.ign
```

The digests are provided to the **coreos-installer** in a later step to validate the authenticity of the Ignition config files on the cluster nodes.

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign ①
```

Example output

```
% Total % Received % Xferd Average Speed Time Time Time Current
          Dload Upload Total Spent Left Speed
0 0 0 0 0 0 0 --:--:--:--:--:-- 0{"ignition":"
{"version":"3.2.0"}, "passwd": {"users": [{"name": "core", "sshAuthorizedKeys": ["ssh-rsa..."]}}
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

- Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

rhcoss-<version>-live.<architecture>.iso

- Use the ISO to start the RHCOS installation. Use one of the following installation options:
 - Burn the ISO image to a disk and boot it directly.
 - Use ISO redirection by using a lights-out management (LOM) interface.
- Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

NOTE

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the **coreos-installer** command as outlined in the following steps, instead of adding kernel arguments.

- Run the **coreos-installer** command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device>
--ignition-hash=SHA512-<digest> ① ②
```

① You must run the **coreos-installer** command by using **sudo**, because the **core** user does not have the required root privileges to perform the installation.

② The **--ignition-hash** option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. **<digest>** is the Ignition config file SHA512 digest obtained in a preceding step.

`<digest>` is the ignition config file SHA512 digest obtained in a preceding step.

NOTE

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running **coreos-installer**.

The following example initializes a bootstrap node installation to the **/dev/sda** device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```
$ sudo coreos-installer install --ignition-
url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-
hash=SHA512-
a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf011
6e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.
10. Continue to create the other machines for your cluster.

IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running `ssh core@<node>.<cluster_name>`. `<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

8.3.14.2. Installing RHCOS by using PXE or iPXE booting

You can use PXE or iPXE booting to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE or iPXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign ①
```

Example output

```
% Total % Received % Xferd Average Speed Time Time Time Current
          Dload Upload Total Spent Left Speed
0 0 0 0 0 0 0 --:--:-- --:--:-- --:--:-- 0{"ignition":
{"version":"3.2.0"}, "passwd": {"users": [{"name": "core", "sshAuthorizedKeys": ["ssh-rsa..."]}}]}
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Obtain the RHCOS **kernel**, **initramfs** and **rootfs** files from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate **kernel**, **initramfs**, and **rootfs** artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel: rhcos-<version>-live-kernel-<architecture>**
- **initramfs: rhcos-<version>-live-initramfs.<architecture>.img**
- **rootfs: rhcos-<version>-live-rootfs.<architecture>.img**

4. Upload the **rootfs**, **kernel**, and **initramfs** files to your HTTP server.

IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.
6. Configure PXE or iPXE installation for the RHCOS images and begin the installation. Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

- For PXE:

```
DEFAULT pxeboot
TIMEOUT 20
PROMPT 0
LABEL pxeboot
KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> ①
APPEND initrd=http://<HTTP_server>/rhcos-<version>-live-initramfs.
<architecture>.img coreos.live.rootfs_url=http://<HTTP_server>/rhcos-<version>-live-
rootfs.<architecture>.img coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign ② ③
```

① Specify the location of the live **kernel** file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

② If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named **eno1**, set **ip=eno1:dhcp**.

- 3** Specify the locations of the RHCOS files that you uploaded to your HTTP server. The **initrd** parameter value is the location of the **initramfs** file, the **coreos.live.rootfs_url**

NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more **console=** arguments to the **APPEND** line. For example, add **console=tty0** **console=ttyS0** to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](#).

- For iPXE:

```
kernel http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> initrd=main
coreos.live.rootfs_url=http://<HTTP_server>/rhcos-<version>-live-rootfs.
<architecture>.img coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign ① ②
initrd --name main http://<HTTP_server>/rhcos-<version>-live-initramfs.
<architecture>.img ③
boot
```

- 1** Specify the locations of the RHCOS files that you uploaded to your HTTP server. The **kernel** parameter value is the location of the **kernel** file, the **initrd=main** argument is needed for booting on UEFI systems, the **coreos.live.rootfs_url** parameter value is the location of the **rootfs** file, and the **coreos.inst.ignition_url** parameter value is the location of the bootstrap Ignition config file.
- 2** If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named **eno1**, set **ip=eno1:dhcp**.
- 3** Specify the location of the **initramfs** file that you uploaded to your HTTP server.

NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more **console=** arguments to the **kernel** line. For example, add **console=tty0** **console=ttyS0** to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](#).

7. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.
9. Continue to create the machines for your cluster.

IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running **ssh core@<node>.<cluster_name>**.

<base_domain> as a user with access to the SSH private key that is paired to the public key that you specified in your **install_config.yaml** file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

8.3.14.3. Advanced RHCOS installation configuration

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:

- Passing kernel arguments to the live installer
- Running **coreos-installer** manually from the live system
- Embedding Ignition configs in an ISO

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

8.3.14.3.1. Using advanced networking options for PXE and ISO installations

Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:

- Pass special kernel parameters when you boot the live installer.
- Use a machine config to copy networking files to the installed system.

- Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

- See the "Advanced RHCOS installation reference" tables.
- Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

Procedure

1. Boot the ISO installer.
2. From the live system shell prompt, configure networking for the live system using available RHEL tools, such as **nmcli** or **nmtui**.
3. Run the **coreos-installer** command to install the system, adding the **--copy-network** option to copy networking configuration. For example:

```
$ coreos-installer install --copy-network \
--ignition-url=http://host/worker.ign /dev/sda
```

IMPORTANT

The **--copy-network** option only copies networking configuration found under **/etc/NetworkManager/system-connections**. In particular, it does not copy the system hostname.

4. Reboot into the installed system.

Additional resources

- See [Getting started with nmcli](#) and [Getting started with nmtui](#) in the RHEL 8 documentation for more information about the **nmcli** and **nmtui** tools.

8.3.14.3.2. Disk partitioning

The disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless the default partitioning configuration is overridden. During the RHCOS installation, the size of the root file system is increased to use the remaining available space on the target device.

There are two cases where you might want to override the default partitioning when installing RHCOS on an OpenShift Container Platform cluster node:

- Creating separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for mounting **/var** or a subdirectory of **/var**, such as **/var/lib/etcd**, on a separate partition, but not both.

IMPORTANT

Kubernetes supports only two file system partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- **Retaining existing partitions:** For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to **coreos-installer** that allow you to retain existing data partitions.

WARNING

The use of custom partitions could result in those partitions not being monitored by OpenShift Container Platform or alerted on. If you are overriding the default partitioning, see [Understanding OpenShift File System Monitoring \(eviction conditions\)](#) for more information about how OpenShift Container Platform monitors your host file systems.

8.3.14.3.2.1. Creating a separate `/var` partition

In general, you should use the default disk partitioning that is created during the RHCOS installation. However, there are cases where you might want to create a separate partition for a directory that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` directory or a subdirectory of `/var`. For example:

- **`/var/lib/containers`:** Holds container-related content that can grow as more images and containers are added to a system.
- **`/var/lib/etcd`:** Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **`/var`:** Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

The use of a separate partition for the `/var` directory or a subdirectory of `/var` also prevents data growth in the partitioned directory from filling up the root file system.

The following procedure sets up a separate `/var` partition by adding a machine config manifest that is wrapped into the Ignition config file for a node type during the preparation phase of an installation.

Procedure

1. On your installation host, change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ openshift-install create manifests --dir=<installation_directory>
```

2. Create a Butane config that configures the additional partition. For example, name the file **\$HOME/clusterconfig/98-var-partition.bu**, change the disk device name to the name of the storage device on the **worker** systems, and set the storage size as appropriate. This example places the **/var** directory on a separate partition:

```
variant: openshift
version: 4.9.0
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
storage:
  disks:
    - device: /dev/<device_name> ①
      partitions:
        - label: var
          start_mib: <partition_start_offset> ②
          size_mib: <partition_size> ③
      filesystems:
        - device: /dev/disk/by-partlabel/var
          path: /var
          format: xfs
          mount_options: [defaults, prjquota] ④
          with_mount_unit: true
```

- ① The storage device name of the disk that you want to partition.
- ② When adding a data partition to the boot disk, a minimum offset value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no offset value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
- ③ The size of the data partition in mebibytes.
- ④ The **prjquota** mount option must be enabled for filesystems used for container storage.

NOTE

When creating a separate **/var** partition, you cannot use different instance types for compute nodes, if the different instance types do not have the same device name.

3. Create a manifest from the Butane config and save it to the **clusterconfig/openshift** directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

4. Create the Ignition config files:

```
$ openshift-install create ignition-configs --dir=<installation_directory> ①
```

- For <installation_directory>, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory:

The files in the <installation_directory>/manifest and <installation_directory>/openshift directories are wrapped into the Ignition config files, including the file that contains the **98-var-partition** custom **MachineConfig** object.

Next steps

- You can apply the custom disk partitioning by referencing the Ignition config files during the RHCOS installations.

8.3.14.3.2.2. Retaining existing partitions

For an ISO installation, you can add options to the **coreos-installer** command that cause the installer to maintain one or more existing partitions. For a PXE installation, you can add **coreos.inst.*** options to the **APPEND** parameter to preserve partitions.

Saved partitions might be data partitions from an existing OpenShift Container Platform system. You can identify the disk partitions you want to keep either by partition label or by number.

NOTE

If you save existing partitions, and those partitions do not leave enough space for RHCOS, the installation will fail without damaging the saved partitions.

Retaining existing partitions during an ISO installation

This example preserves any partition in which the partition label begins with **data** (**data***):

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
--save-partlabel 'data*' /dev/sda
```

The following example illustrates running the **coreos-installer** in a way that preserves the sixth (6) partition on the disk:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
--save-partindex 6 /dev/sda
```

This example preserves partitions 5 and higher:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign
--save-partindex 5- /dev/sda
```

In the previous examples where partition saving is used, **coreos-installer** recreates the partition immediately.

Retaining existing partitions during a PXE installation

This **APPEND** option preserves any partition in which the partition label begins with 'data' ('data*'):

```
coreos.inst.save_partlabel=data*
```

This **APPEND** option preserves partitions 5 and higher:

```
coreos.inst.save_partindex=5-
```

This **APPEND** option preserves partition 6:

```
coreos.inst.save_partindex=6
```

8.3.14.3.3. Identifying Ignition configs

When doing an RHCOS manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

- **Permanent install Ignition config:** Every manual RHCOS installation needs to pass one of the Ignition config files generated by **openshift-installer**, such as **bootstrap.ign**, **master.ign** and **worker.ign**, to carry out the installation.

IMPORTANT

It is not recommended to modify these Ignition config files directly. You can update the manifest files that are wrapped into the Ignition config files, as outlined in examples in the preceding sections.

For PXE installations, you pass the Ignition configs on the **APPEND** line using the **coreos.inst.ignition_url=** option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the **coreos-installer** command line with the **--ignition-url=** option. In both cases, only HTTP and HTTPS protocols are supported.

- **Live install Ignition config:** This type must be created manually and should be avoided if possible, as it is not supported by Red Hat. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before and/or after the RHCOS system installs to disk. This method should only be used for performing tasks that must be done once and not applied again later, such as with advanced partitioning that cannot be done using a machine config.

For PXE or ISO boots, you can create the Ignition config and **APPEND** the **ignition.config.url=** option to identify the location of the Ignition config. You also need to append **ignition.firstboot** **ignition.platform.id=metal** or the **ignition.config.url** option will be ignored.

8.3.14.3.3.1. Embedding a live install Ignition config in the RHCOS ISO

You can embed a live install Ignition config directly in an RHCOS ISO image. When the ISO image is booted, the embedded config will be applied automatically.

Procedure

1. Download the **coreos-installer** binary from the following image mirror page: <https://mirror.openshift.com/pub/openshift-v4/clients/coreos-installer/latest/>.
2. Retrieve the RHCOS ISO image and the Ignition config file, and copy them into an accessible directory, such as **/mnt**:

```
# cp rhcos-<version>-live.x86_64.iso bootstrap.ign /mnt/
# chmod 644 /mnt/rhcos-<version>-live.x86_64.iso
```

3. Run the following command to embed the Ignition config into the ISO:

```
# ./coreos-installer iso ignition embed -i /mnt/bootstrap.ign \
/mnt/rhcos-<version>-live.x86_64.iso
```

You can now use that ISO to install RHCOS using the specified live install Ignition config.

IMPORTANT

Using **coreos-installer iso ignition embed** to embed a file generated by **openshift-installer**, such as **bootstrap.ign**, **master.ign** and **worker.ign**, is unsupported and not recommended.

4. To show the contents of the embedded Ignition config and direct it into a file, run:

```
# ./coreos-installer iso ignition show /mnt/rhcos-<version>-live.x86_64.iso > mybootstrap.ign
# diff -s bootstrap.ign mybootstrap.ign
```

Example output

```
Files bootstrap.ign and mybootstrap.ign are identical
```

5. To remove the Ignition config and return the ISO to its pristine state so you can reuse it, run:

```
# ./coreos-installer iso ignition remove /mnt/rhcos-<version>-live.x86_64.iso
```

You can now embed another Ignition config into the ISO or use the ISO in its pristine state.

8.3.14.3.4. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the **coreos-installer** command.

8.3.14.3.4.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

IMPORTANT

When adding networking arguments manually, you must also add the **rd.neednet=1** kernel argument to bring the network up in the initramfs.

The following table provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the **ip=**, **nameserver=**, and **bond=** kernel arguments.

NOTE

Ordering is important when adding the kernel arguments: **ip=**, **nameserver=**, and then **bond=**.

The networking options are passed to the **dracut** tool during system boot. For more information about the networking options supported by **dracut**, see the **dracut.cmdline** manual page.

Table 8.30. Networking and bonding options for ISO installations

Description	Examples
<p>To configure an IP address, either use DHCP (ip=dhcp) or set an individual static IP address (ip=<host_ip>). If setting a static IP, you must then identify the DNS server IP address (nameserver=<dns_ip>) on each node. This example sets:</p> <ul style="list-style-type: none"> • The node's IP address to 10.10.10.2 • The gateway address to 10.10.10.254 • The netmask to 255.255.255.0 • The hostname to core0.example.com • The DNS server address to 4.4.4.41 • The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically. 	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none nameserver=4.4.4.41</pre>

NOTE

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

Description	Examples
<p>Specify multiple network interfaces by specifying multiple ip= entries.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none</pre>
<p>Optional: You can configure routes to additional networks by setting an rd.route= value.</p> <p>If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.</p>	<p>To configure the default gateway:</p> <pre>ip=:10.10.10.254:::</pre> <p>To configure the route for the additional network:</p> <pre>rd.route=20.20.20.0/24:20.20.20.254:enp2s0</pre>
<p>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the enp1s0 interface has a static networking configuration and DHCP is disabled for enp2s0, which is not used.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ip=:core0.example.com:enp2s0:none</pre>

Description	Examples
<p>You can combine DHCP and static IP configurations on systems with multiple network interfaces.</p>	<pre data-bbox="817 258 1436 370">ip=enp1s0:dhcp ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp2s0:none</pre>
<p>Optional: You can configure VLANs on individual interfaces by using the vlan= parameter.</p>	<p>To configure a VLAN on a network interface and use a static IP address:</p> <pre data-bbox="849 539 1436 651">ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp2s0.100:none vlan=enp2s0.100:enp2s0</pre> <p>To configure a VLAN on a network interface and to use DHCP:</p> <pre data-bbox="849 808 1166 875">ip=enp2s0.100:dhcp vlan=enp2s0.100:enp2s0</pre>
<p>You can provide multiple DNS servers by adding a nameserver= entry for each server.</p>	<pre data-bbox="849 977 1102 1044">nameserver=1.1.1.1 nameserver=8.8.8.8</pre>
<p>Optional: Bonding multiple network interfaces to a single interface is supported using the bond= option. In these two examples:</p> <ul style="list-style-type: none"> ● The syntax for configuring a bonded interface is: bond=name[:network_interfaces] [:options] <i>name</i> is the bonding device name (bond0), <i>network_interfaces</i> represents a comma-separated list of physical (ethernet) interfaces (em1,em2), and <i>options</i> is a comma-separated list of bonding options. Enter modinfo bonding to see available options. ● When you create a bonded interface using bond=, you must specify how the IP address is assigned and other information for the bonded interface. 	<p>To configure the bonded interface to use DHCP, set the bond's IP address to dhcp. For example:</p> <pre data-bbox="849 1224 1404 1291">bond=bond0:em1,em2:mode=active-backup ip=bond0:dhcp</pre> <p>To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:</p> <pre data-bbox="849 1482 1436 1594">bond=bond0:em1,em2:mode=active-backup ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:bond0:none</pre>

Description	Examples
Optional: You can configure VLANs on bonded interfaces by using the vlan= parameter.	To configure the bonded interface with a VLAN and to use DHCP: ip=bond0.100:dhcp bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0
	To configure the bonded interface with a VLAN and to use a static IP address: ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:bond0.100:none bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0

8.3.14.3.4.2. coreos-installer options for ISO installations

You can install RHCOS by running **coreos-installer install <options> <device>** at the command prompt, after booting into the RHCOS live environment from an ISO image.

The following table shows the subcommands, options, and arguments you can pass to the **coreos-installer** command.

Table 8.31. coreos-installer subcommands, command-line options, and arguments

coreos-installer install subcommand	
<i>Subcommand</i>	<i>Description</i>
\$ coreos-installer install <options> <device>	Embed an Ignition config in an ISO image.
coreos-installer install subcommand options	
<i>Option</i>	<i>Description</i>
-u, --image-url <url>	Specify the image URL manually.
-f, --image-file <path>	Specify a local image file manually. Used for debugging.
-i, --ignition-file <path>	Embed an Ignition config from a file.
-l, --ignition-url <URL>	Embed an Ignition config from a URL.
--ignition-hash <digest>	Digest type-value of the Ignition config.

-p, --platform <name>	Override the Ignition platform ID for the installed system.
--append-karg <arg>...	Append a default kernel argument to the installed system.
--delete-karg <arg>...	Delete a default kernel argument from the installed system.
-n, --copy-network	Copy the network configuration from the install environment. +
	<p>IMPORTANT</p> <p>The --copy-network option only copies networking configuration found under /etc/NetworkManager/system-connections. In particular, it does not copy the system hostname.</p>
--network-dir <path>	For use with -n . Default is /etc/NetworkManager/system-connections/ .
--save-partlabel <lx>..	Save partitions with this label glob.
--save-partindex <id>...	Save partitions with this number or range.
--insecure	Skip signature verification.
--insecure-ignition	Allow Ignition URL without HTTPS or hash.
--architecture <name>	Target CPU architecture. Default is x86_64 .
--preserve-on-error	Do not clear partition table on error.
-h, --help	Print help information.
coreos-install install subcommand argument	
<i>Argument</i>	<i>Description</i>
<device>	The destination device.
coreos-installer ISO Ignition subcommands	
<i>Subcommand</i>	<i>Description</i>

\$ coreos-installer iso ignition embed <options> --ignition-file <file_path> <ISO_image>	Embed an Ignition config in an ISO image.
coreos-installer iso ignition show <options> <ISO_image>	Show the embedded Ignition config from an ISO image.
coreos-installer iso ignition remove <options> <ISO_image>	Remove the embedded Ignition config from an ISO image.
coreos-installer ISO Ignition subcommand options	
<i>Option</i>	<i>Description</i>
-f, --force	Overwrite an existing Ignition config.
-i, --ignition-file <path>	The Ignition config to be used. Default is stdin .
-o, --output <path>	Write the ISO to a new output file.
-h, --help	Print help information.
coreos-installer PXE Ignition subcommands	
<i>Subcommand</i>	<i>Description</i>
Note that not all of these options are accepted by all subcommands.	
coreos-installer pxe ignition wrap <options>	Wrap an Ignition config in an image.
coreos-installer pxe ignition unwrap <options> <image_name>	Show the wrapped Ignition config in an image.
coreos-installer PXE Ignition subcommand options	
<i>Option</i>	<i>Description</i>
Note that not all of these options are accepted by all subcommands.	
-i, --ignition-file <path>	The Ignition config to be used. Default is stdin .
-o, --output <path>	Write the ISO to a new output file.
-h, --help	Print help information.

8.3.14.3.4.3. coreos.inst boot options for ISO or PXE installations

You can automatically invoke **coreos-installer** options at boot time by passing **coreos.inst** boot arguments to the RHCOS live installer. These are provided in addition to the standard boot arguments.

- For ISO installations, the **coreos.inst** options can be added by interrupting the automatic boot at the bootloader menu. You can interrupt the automatic boot by pressing **TAB** while the **RHEL CoreOS (Live)** menu option is highlighted.
- For PXE or iPXE installations, the **coreos.inst** options must be added to the **APPEND** line before the RHCOS live installer is booted.

The following table shows the RHCOS live installer **coreos.inst** boot options for ISO and PXE installations.

Table 8.32. coreos.inst boot options

Argument	Description
coreos.inst.install_dev	Required. The block device on the system to install to. It is recommended to use the full path, such as /dev/sda , although sda is allowed.
coreos.inst.ignition_url	Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded. Only HTTP and HTTPS protocols are supported.
coreos.inst.save_partlabel	Optional: Comma-separated labels of partitions to preserve during the install. Glob-style wildcards are permitted. The specified partitions do not need to exist.
coreos.inst.save_partindex	Optional: Comma-separated indexes of partitions to preserve during the install. Ranges m-n are permitted, and either m or n can be omitted. The specified partitions do not need to exist.
coreos.inst.insecure	Optional: Permits the OS image that is specified by coreos.inst.image_url to be unsigned.

Argument	Description
coreos.inst.image_url	<p>Optional: Download and install the specified RHCOS image.</p> <ul style="list-style-type: none"> ● This argument should not be used in production environments and is intended for debugging purposes only. ● While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install. ● If you are using coreos.inst.image_url, you must also use coreos.inst.insecure. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform. ● Only HTTP and HTTPS protocols are supported.
coreos.inst.skip_reboot	<p>Optional: The system will not reboot after installing. After the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only.</p>
coreos.inst.platform_id	<p>Optional: The Ignition platform ID of the platform the RHCOS image is being installed on. Default is metal. This option determines whether or not to request an Ignition config from the cloud provider, such as VMware. For example: coreos.inst.platform_id=vmware.</p>
ignition.config.url	<p>Optional: The URL of the Ignition config for the live boot. For example, this can be used to customize how coreos-installer is invoked, or to run code before or after the installation. This is different from coreos.inst.ignition_url, which is the Ignition config for the installed system.</p>

8.3.14.4. Enabling multipathing with kernel arguments on RHCOS

RHCOS supports multipathing on the primary disk, allowing stronger resilience to hardware failure to achieve higher host availability.

You can enable multipathing at installation time for nodes that were provisioned in OpenShift Container Platform 4.8 or later. While post-installation support is available by activating multipathing via the machine config, enabling multipathing during installation is recommended.

In setups where any I/O to non-optimized paths results in I/O system errors, you must enable multipathing at installation time.

IMPORTANT

On IBM Z and LinuxONE, you can enable multipathing only if you configured your cluster for it during installation. For more information, see "Installing RHCOS and starting the OpenShift Container Platform bootstrap process" in *Installing a cluster with z/VM on IBM Z and LinuxONE*.

The following procedure enables multipath at installation time and appends kernel arguments to the **coreos-installer install** command so that the installed system itself will use multipath beginning from the first boot.

Prerequisites

- You have a running OpenShift Container Platform cluster that uses version 4.8 or later.
- You are logged in to the cluster as a user with administrative privileges.

Procedure

1. To enable multipath and start the **multipathd** daemon, run the following command:

```
$ mpathconf --enable && systemctl start multipathd.service
```

- Optional: If booting the PXE or ISO, you can instead enable multipath by adding **rd.multipath=default** from the kernel command line.

2. Append the kernel arguments by invoking the **coreos-installer** program:

- If there is only one multipath device connected to the machine, it should be available at path **/dev/mapper/mpatha**. For example:

```
$ coreos-installer install /dev/mapper/mpatha \ ①  
--append-karg rd.multipath=default \  
--append-karg root=/dev/disk/by-label/dm-mpath-root
```

① Indicates the path of the single multipathed device.

- If there are multiple multipath devices connected to the machine, or to be more explicit, instead of using **/dev/mapper/mpatha**, it is recommended to use the World Wide Name (WWN) symlink available in **/dev/disk/by-id**. For example:

```
$ coreos-installer install /dev/disk/by-id/wwn-<wwn_ID> \ ①  
--append-karg rd.multipath=default \  
--append-karg root=/dev/disk/by-label/dm-mpath-root
```

① Indicates the WWN ID of the target multipathed device. For example, **0xx194e957fcedb4841**.

This symlink can also be used as the **coreos.inst.install_dev** kernel argument when using special **coreos.inst.*** arguments to direct the live installer. For more information, see "Installing RHCOS and starting the OpenShift Container Platform bootstrap process".

- Check that the kernel arguments worked by going to one of the worker nodes and listing the kernel command line arguments (in **/proc/cmdline** on the host):

```
$ oc debug node/ip-10-0-141-105.ec2.internal
```

Example output

```
Starting pod/ip-10-0-141-105ec2internal-debug ...
To use host binaries, run `chroot /host`

sh-4.2# cat /host/proc/cmdline
...
rd.multipath=default root=/dev/disk/by-label/dm-mpath-root
...
sh-4.2# exit
```

You should see the added kernel arguments.

8.3.14.5. Updating the bootloader using bootupd

To update the bootloader by using **bootupd**, you must either install **bootupd** on RHCOS machines manually or provide a machine config with the enabled **systemd** unit. Unlike **grubby** or other bootloader tools, **bootupd** does not manage kernel space configuration such as passing kernel arguments.

After you have installed **bootupd**, you can manage it remotely from the OpenShift Container Platform cluster.

NOTE

It is recommended that you use **bootupd** only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

Manual install method

You can manually install **bootupd** by using the **bootctl** command-line tool.

- Inspect the system status:

```
# bootupctl status
```

Example output

```
Component EFI
Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
Update: At latest version
```

- RHCOS images created without **bootupd** installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

```
# bootupctl adopt-and-update
```

Example output

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

```
# bootupctl update
```

Example output

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

Machine config method

Another way to enable **bootupd** is by providing a machine config.

- Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

Example output

```
variant: rhcos
version: 1.1.0
systemd:
  units:
    - name: custom-bootupd-auto.service
      enabled: true
      contents: |
        [Unit]
        Description=Bootupd automatic update

        [Service]
        ExecStart=/usr/bin/bootupctl update
        RemainAfterExit=yes

        [Install]
        WantedBy=multi-user.target
```

8.3.15. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.

- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

```
$ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \ ①
--log-level=info ②
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.22.1 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

IMPORTANT

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

Additional resources

- See [Monitoring installation progress](#) for more information about monitoring the installation logs and retrieving diagnostic data if installation issues arise.

8.3.16. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.

- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- ① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

8.3.17. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

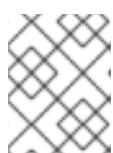

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.22.1
master-1	Ready	master	63m	v1.22.1
master-2	Ready	master	64m	v1.22.1

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-8b2br	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
csr-8vnps	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
...			

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

- ① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	Pending
csr-c571v	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	Pending
...			

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{{if not .status}}}{{.metadata.name}}\n{{end}}{{end}}' | xargs oc adm certificate approve
```

- After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	73m	v1.22.1
master-1	Ready	master	73m	v1.22.1
master-2	Ready	master	74m	v1.22.1
worker-0	Ready	worker	11m	v1.22.1
worker-1	Ready	worker	11m	v1.22.1

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

8.3.18. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

- Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.9.0	True	False	False 19m
baremetal	4.9.0	True	False	False 37m
cloud-credential	4.9.0	True	False	False 40m
cluster-autoscaler	4.9.0	True	False	False 37m
config-operator	4.9.0	True	False	False 38m
console	4.9.0	True	False	False 26m

service-ca	4.9.0	True	False	False 38m
storage	4.9.0	True	False	False 37m

2. Configure the Operators that are not available.

Additional resources

- See [Gathering logs from a failed installation](#) for details about gathering data in the event of a failed OpenShift Container Platform installation.
- See [Troubleshooting Operator issues](#) for steps to check Operator pod health across the cluster and gather Operator logs for diagnosis.

8.3.18.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the **managementState** from **Removed** to **Managed**.

NOTE

The Prometheus console provides an **ImageRegistryRemoved** alert, for example:

"Image Registry has been removed. **ImageStreamTags**, **BuildConfigs** and **DeploymentConfigs** which reference **ImageStreamTags** may not work as expected. Please configure storage and update the config to **Managed** state by editing configs.imageregistry.operator.openshift.io."

8.3.18.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

8.3.18.3. Configuring block registry storage

To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

IMPORTANT

Block storage volumes are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

Procedure

- To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only one (1) replica:

```
$ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy":"Recreate","replicas":1}}'
```

- Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.
- Edit the registry configuration so that it references the correct PVC.

8.3.19. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

- Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.9.0	True	False	False 19m
baremetal	4.9.0	True	False	False 37m
cloud-credential	4.9.0	True	False	False 40m
cluster-autoscaler	4.9.0	True	False	False 37m
config-operator	4.9.0	True	False	False 38m
console	4.9.0	True	False	False 26m
csi-snapshot-controller	4.9.0	True	False	False 37m
dns	4.9.0	True	False	False 37m
etcd	4.9.0	True	False	False 36m
image-registry	4.9.0	True	False	False 31m
ingress	4.9.0	True	False	False 30m
insights	4.9.0	True	False	False 31m
kube-apiserver	4.9.0	True	False	False 26m
kube-controller-manager	4.9.0	True	False	False 36m
kube-scheduler	4.9.0	True	False	False 36m
kube-storage-version-migrator	4.9.0	True	False	False 37m
machine-api	4.9.0	True	False	False 29m
machine approver	4.9.0	True	False	False 37m
machine-config	4.9.0	True	False	False 36m
marketplace	4.9.0	True	False	False 37m
monitoring	4.9.0	True	False	False 29m
network	4.9.0	True	False	False 38m

node-tuning	4.9.0	True	False	False	37m
openshift-apiserver	4.9.0	True	False	False	32m
openshift-controller-manager	4.9.0	True	False	False	30m
openshift-samples	4.9.0	True	False	False	32m
operator-lifecycle-manager	4.9.0	True	False	False	37m
operator-lifecycle-manager-catalog	4.9.0	True	False	False	37m
operator-lifecycle-manager-packageserver	4.9.0	True	False	False	32m
service-ca	4.9.0	True	False	False	38m
storage	4.9.0	True	False	False	37m

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete ①
```

- ① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.

- a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

Example output

NAMESPACE	NAME	READY	STATUS
RESTARTS	AGE		
openshift-apiserver-operator	openshift-apiserver-operator-85cb746d55-zqhs8	1/1	
Running 1 9m			
openshift-apiserver	apiserver-67b9g	1/1	Running 0
3m			
openshift-apiserver	apiserver-ljcmx	1/1	Running 0
1m			

openshift-apiserver	apiserver-z25h4	1/1	Running	0
2m				
openshift-authentication-operator	authentication-operator-69d5d8bf84-vh2n8	1/1		
Running	0	5m		

...

- b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> ①
```

- ① Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.
See "Enabling multipathing with kernel arguments on RHCOS" in the *Post-installation machine configuration tasks* documentation for more information.

8.3.20. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

8.3.21. Next steps

- [Validating an installation](#).
- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- [Set up your registry and configure registry storage](#).

8.4. INSTALLING A USER-PROVISIONED BARE METAL CLUSTER ON A RESTRICTED NETWORK

In OpenShift Container Platform 4.9, you can install a cluster on bare metal infrastructure that you provision in a restricted network.

IMPORTANT

While you might be able to follow this procedure to deploy a cluster on virtualized or cloud environments, you must be aware of additional considerations for non-bare metal platforms. Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you attempt to install an OpenShift Container Platform cluster in such an environment.

8.4.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [created a registry on your mirror host](#) and obtained the **imageContentSources** data for your version of OpenShift Container Platform.

IMPORTANT

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You provisioned [persistent storage](#) for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- If you use a firewall and plan to use the Telemetry service, you [configured the firewall to allow the sites](#) that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

8.4.2. About installations in restricted networks

In OpenShift Container Platform 4.9, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service's IAM service, require internet access, so you might still require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

8.4.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

8.4.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

8.4.4. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

8.4.4.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

Table 8.33. Minimum required hosts

Hosts	Description
One temporary bootstrap machine	The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.
Three control plane machines	The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.
At least two compute machines, which are also known as worker machines.	The workloads requested by OpenShift Container Platform users run on the compute machines.

NOTE

As an exception, you can run zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production. Running one compute machine is not supported.

IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 7.9, or RHEL 8.4.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

8.4.4.2. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

Machine	Operating System	CPU [1]	RAM	Storage	IOPS [2]
Bootstrap	RHCOS	4	16 GB	100 GB	300
Control plane	RHCOS	4	16 GB	100 GB	300
Compute	RHCOS, RHEL 7.9, or RHEL 8.4 [3]	2	8 GB	100 GB	300

1. One CPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = CPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

8.4.4.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

Additional resources

- See [Configuring a three-node cluster](#) for details about deploying three-node clusters in bare metal environments.
- See [Approving the certificate signing requests for your machines](#) for more information about approving cluster certificate signing requests after installation.

8.4.4.4. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.

NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

8.4.4.4.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

8.4.4.4.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

Table 8.34. Ports used for all-machine to all-machine communications

Protocol	Port	Description
ICMP	N/A	Network reachability tests
TCP	1936	Metrics
	9000-9999	Host level services, including the node exporter on ports 9100-9101 and the Cluster Version Operator on port 9099 .
	10250-10259	The default ports that Kubernetes reserves
	10256	openshift-sdn
UDP	4789	VXLAN and Geneve
	6081	VXLAN and Geneve

Protocol	Port	Description
	9000-9999	Host level services, including the node exporter on ports 9100-9101 .
TCP/UDP	30000-32767	Kubernetes node port

Table 8.35. Ports used for all-machine to control plane communications

Protocol	Port	Description
TCP	6443	Kubernetes API

Table 8.36. Ports used for control plane machine to control plane machine communications

Protocol	Port	Description
TCP	2379-2380	etcd server and peer ports

NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for [Configuring chrony time service](#).

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

Additional resources

- [Configuring chrony time service](#)

8.4.4.5. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are

provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

NOTE

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the *DHCP recommendations for user-provisioned infrastructure* section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, **<cluster_name>** is the cluster name and **<base_domain>** is the base domain that you specify in the **install-config.yaml** file. A complete DNS record takes the form: **<component>.<cluster_name>.<base_domain>..**

Table 8.37. Required DNS records

Component	Record	Description
Kubernetes API	api.<cluster_name>.<base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.
	api-int.<cluster_name>.<base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.
Routes	*.apps.<cluster_name>.<base_domain>.	<p>IMPORTANT</p> <p>The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</p>
		<p>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</p> <p>For example, console-openshift-console.apps.<cluster_name>.<base_domain> is used as a wildcard route to the OpenShift Container Platform console.</p>
Bootstrap machine	bootstrap.<cluster_name>.<base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.

Component	Record	Description
Control plane machine s	<master><n>. <cluster_name>. <base_domain>.	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.
Compute machine s	<worker><n>. <cluster_name>. <base_domain>.	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

NOTE

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

TIP

You can use the **dig** command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

8.4.4.5.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is **ocp4** and the base domain is **example.com**.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

Example 8.7. Sample DNS zone database

```
$TTL 1W
@ IN SOA ns1.example.com. root (

;
:EOF

```

- ① Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
- ② Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
- ③ Provides reverse DNS resolution for the bootstrap machine.
- ④ ⑤ ⑥ Provides reverse DNS resolution for the control plane machines.
- ⑦ ⑧ Provides reverse DNS resolution for the compute machines.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

Additional resources

- [Validating DNS resolution for user-provisioned infrastructure](#)

8.4.4.6. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer:** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
 - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI)

for the API routes.

- A stateless load balancing algorithm. The options vary based on the load balancer implementation.

NOTE

Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

Table 8.38. API load balancer

Port	Back-end machines (pool members)	Internal	External	Description
6443	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.	X	X	Kubernetes API server
22623	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.	X		Machine config server

NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the **/readyz** endpoint to the removal of the API server instance from the pool. Within the time frame after **/readyz** returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer.** Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 8.39. Application ingress load balancer

Port	Back-end machines (pool members)	Internal	External	Description
443	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTPS traffic
80	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTP traffic

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

NOTE

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

8.4.4.6.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an **/etc/haproxy/haproxy.cfg** configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 8.9. Sample API and application ingress load balancer configuration

```
global
log    127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000
daemon
defaults
mode      http
log       global
option    dontlognull
option http-server-close
```

```

option          redispatch
retries        3
timeout http-request 10s
timeout queue   1m
timeout connect 10s
timeout client   1m
timeout server   1m
timeout http-keep-alive 10s
timeout check    10s
maxconn       3000
frontend stats
  bind *:1936
  mode      http
  log       global
  maxconn  10
  stats enable
  stats hide-version
  stats refresh 30s
  stats show-node
  stats show-desc Stats for ocp4 cluster 1
  stats auth admin:ocp4
  stats uri /stats
listen api-server-6443 2
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup 3
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623 4
  bind *:22623
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup 5
  server master0 master0.ocp4.example.com:22623 check inter 1s
  server master1 master1.ocp4.example.com:22623 check inter 1s
  server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443 6
  bind *:443
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:443 check inter 1s
  server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80 7
  bind *:80
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:80 check inter 1s
  server worker1 worker1.ocp4.example.com:80 check inter 1s

```

1 In the example, the cluster name is **ocp4**.

2 Port **6443** handles the Kubernetes API traffic and points to the control plane machines.

3 **5** The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

- 4 Port **22623** handles the machine config server traffic and points to the control plane machines.
- 6 Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
- 7 Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

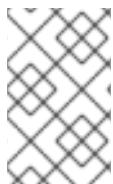

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltpu** on the HAProxy node.

NOTE

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy_connect_any=1**.

8.4.5. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

Prerequisites

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.

- a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
- b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

NOTE

If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

- c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the *Setting the cluster node hostnames through DHCP* section for details about hostname considerations.

NOTE

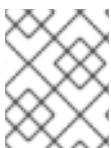

If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.
3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.
4. Setup the required DNS infrastructure for your cluster.
 - a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
 - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.
5. Validate your DNS configuration.
 - a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
 - b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.

See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.

- Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

NOTE

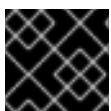

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

Additional resources

- [Requirements for a cluster with user-provisioned infrastructure](#)
- [Installing RHCOS and starting the OpenShift Container Platform bootstrap process](#)
- [Setting the cluster node hostnames through DHCP](#)
- [Advanced RHCOS installation configuration](#)
- [Networking requirements for user-provisioned infrastructure](#)
- [User-provisioned DNS requirements](#)
- [Validating DNS resolution for user-provisioned infrastructure](#)
- [Load balancing requirements for user-provisioned infrastructure](#)

8.4.6. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

- From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
 - Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> 1
```

- Replace **<nameserver_ip>** with the IP address of the nameserver, **<cluster_name>** with your cluster name, and **<base_domain>** with your base domain name.

Example output

```
api.ocp4.example.com. 0 IN A 192.168.1.5
```

- b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

```
api-int.ocp4.example.com. 0 IN A 192.168.1.5
```

- c. Test an example ***.apps.<cluster_name>.<base_domain>** DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

```
random.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace **random** with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

- d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

- e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.
 - a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. ①
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. ②
```

- ① Provides the record name for the Kubernetes internal API.
- ② Provides the record name for the Kubernetes API.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

- b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

- c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

- [User-provisioned DNS requirements](#)
- [Load balancing requirements for user-provisioned infrastructure](#)

8.4.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added

to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> ①
```

- 1 Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> ①
```

- ① Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

Additional resources

- [Verifying node health](#)

8.4.8. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain the **imageContentSources** section from the output of the command to mirror the repository.
- Obtain the contents of the certificate for your mirror registry.

Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation_directory>**.

NOTE

You must name this configuration file **install-config.yaml**.

- Unless you use a registry that RHCOS trusts by default, such as **docker.io**, you must provide the contents of the certificate for your mirror repository in the **additionalTrustBundle** section. In most cases, you must provide the certificate for your mirror.
- You must include the **imageContentSources** section from the output of the command to mirror the repository.

NOTE

For some platform types, you can alternatively run **./openshift-install create install-config --dir=<installation_directory>** to generate an **install-config.yaml** file. You can provide details about your cluster configuration at the prompts.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

8.4.8.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster's platform. When you create the **install-config.yaml** installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the **install-config.yaml** file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

IMPORTANT

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

8.4.8.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 8.40. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>. <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object

Parameter	Description	Values
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code> .	String of lowercase letters, hyphens (-), and periods (.), such as dev .
platform	The configuration for the specific platform upon which to perform the installation: aws , baremetal , azure , openstack , ovirt , vsphere , or <code>{}</code> . For additional information about platform <code><platform></code> parameters, consult the table for your specific platform that follows.	Object
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths":{ "cloud.openshift.com":{ "auth":"b3Blb=", "email":"you@example.com" }, "quay.io":{ "auth":"b3Blb=", "email":"you@example.com" } } }</pre>

8.4.8.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 8.41. Network parameters

Parameter	Description	Values
-----------	-------------	--------

Parameter	Description	Values
networking	The configuration for the cluster network.	<p>Object</p>  <p>NOTE</p> <p>You cannot modify parameters specified by the networking object after installation.</p>
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	<p>The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>	<p>An array of objects. For example:</p> <pre>networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</pre>
networking.clusterNetwork.cidr	<p>Required if you use networking.clusterNetwork. An IP address block.</p> <p>An IPv4 network.</p>	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{(32 - 23)} - 2$) pod IP addresses.	<p>A subnet prefix.</p> <p>The default value is 23.</p>
networking.serviceNetwork	<p>The IP address block for services. The default value is 172.30.0.0/16.</p> <p>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</p>	<p>An array with an IP address block in CIDR format. For example:</p> <pre>networking: serviceNetwork: - 172.30.0.0/16</pre>

Parameter	Description	Values
networking.machineNetwork	The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.	An array of objects. For example: <pre>networking: machineNetwork: - cidr: 10.0.0.0/16</pre>
networking.machineNetwork.cidr	Required if you use networking.machineNetwork . An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24 .	An IP network block in CIDR notation. For example, 10.0.0.0/16 .  NOTE Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

8.4.8.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 8.42. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String

Parameter	Description	Values
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	 IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws , azure , gcp , openstack , ovirt , vsphere , or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String

Parameter	Description	Values
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	 IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.
credentialsMode	The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.	Mint, Passthrough, Manual , or an empty string ("").
	 NOTE Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the <i>Cloud Credential Operator</i> entry in the <i>Red Hat Operators</i> reference content.	

Parameter	Description	Values
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	false or true
imageContentSources	Sources and repositories for the release-image content.	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	<p>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</p>	<p>Internal or External. The default value is External.</p> <p>Setting this field to Internal is not supported on non-cloud platforms.</p>

Parameter	Description	Values
sshKey	<p>The SSH key or keys to authenticate access your cluster machines.</p>  <p>NOTE</p> <p>For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.</p>	<p>One or more keys. For example:</p> <pre>sshKey: <key1> <key2> <key3></pre>

8.4.8.2. Sample install-config.yaml file for bare metal

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

- mirrors:
 - <local_registry>/<local_repository_name>/release
source: quay.io/openshift-release-dev/ocp-release
 - mirrors:
 - <local_registry>/<local_repository_name>/release
source: quay.io/openshift-release-dev/ocp-v4.0-art-dev

1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2 5 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

3 6 Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

IMPORTANT

If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

4 You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

- 7** The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.
- 8** The cluster name that you specified in your DNS records.
- 9** A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

- 10 The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to **23**, then each node is assigned a /23 subnet out of the given **cidr**, which allows for 510 ($2^{(32 - 23)} - 2$)
- 11 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.
- 12 You must set the platform to **none**. You cannot provide additional platform configuration variables for your platform.

WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as [installing a cluster on any platform](#), and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.
2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

- 13 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

- 14 For **<local_registry>**, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, **registry.example.com** or **registry.example.com:5000**. For **<credentials>**, specify the base64-encoded user name and password for your mirror registry.
- 15 The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- 16 Provide the contents of the certificate file that you used for your mirror registry.

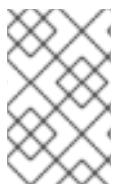

- 17** Provide the **imageContentSources** section from the output of the command to mirror the repository.

Additional resources

- See [Load balancing requirements for user-provisioned infrastructure](#) for more information on the API and application ingress load balancing requirements.

8.4.8.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

NOTE

For bare metal installations, if you do not assign node IP addresses from the range that is specified in the **networking.machineNetwork[].cidr** field in the **install-config.yaml** file, you must include them in the **proxy.noProxy** field.

Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

- If your cluster is on AWS, you added the **ec2.<region>.amazonaws.com**, **elasticloadbalancing.<region>.amazonaws.com**, and **s3.<region>.amazonaws.com** endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
```

```

proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
  additionalTrustBundle: | 4
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
...

```

- 1** A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpProxy** value.
- 2** A proxy URL to use for creating HTTPS connections outside the cluster. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpsProxy** value.
- 3** A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use `*` to bypass the proxy for all destinations.
- 4** If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace to hold the additional CA certificates. If you provide **additionalTrustBundle** and at least one proxy setting, the **Proxy** object is configured to reference the **user-ca-bundle** config map in the **trustedCA** field. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges the contents specified for the **trustedCA** parameter with the RHCOS trust bundle. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE

The installation program does not support the proxy **readinessEndpoints** field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

8.4.8.4. Configuring a three-node cluster

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing **install-config.yaml** file.

Procedure

- Ensure that the number of compute replicas is set to **0** in your **install-config.yaml** file, as shown in the following **compute** stanza:

```
compute:
- name: worker
  platform: {}
  replicas: 0
```

NOTE

You must set the value of the **replicas** parameter for the compute machines to **0** when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.
- When you create the Kubernetes manifest files in the following procedure, ensure that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file is set to **true**. This enables your application workloads to run on the control plane nodes.
- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

8.4.9. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the **install-config.yaml** installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

Example output

```
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift
```

- 1 For **<installation_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

WARNING

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

2. Check that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
 - a. Open the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file.
 - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
 - c. Save and exit the file.

- To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory> ①
```

- For **<installation_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation_directory>/auth** directory:

```

    auth
      kubeadmin-password
      kubeconfig
    bootstrap.ign
    master.ign
    metadata.json
    worker.ign
  
```

Additional resources

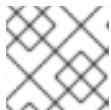

- See [Recovering from expired control plane certificates](#) for more information about recovering kubelet certificates.

8.4.10. Configuring chrony time service

You must set the time server and related settings used by the chrony time service (**chronyd**) by modifying the contents of the **chrony.conf** file and passing those contents to your nodes as a machine config.

Procedure

- Create a Butane config including the contents of the **chrony.conf** file. For example, to configure chrony on worker nodes, create a **99-worker-chrony.bu** file.

NOTE

See "Creating machine configs with Butane" for information about Butane.

```

variant: openshift
version: 4.9.0
metadata:
  name: 99-worker-chrony ①
  labels:
    machineconfiguration.openshift.io/role: worker ②
storage:
  files:
    - path: /etc/chrony.conf
      mode: 0644
      overwrite: true
      contents:
        ...
  
```

```
inline: |
  pool 0.rhel.pool.ntp.org iburst ③
  driftfile /var/lib/chrony/drift
  makestep 1.0 3
  rtcsync
  logdir /var/log/chrony
```

① ② On control plane nodes, substitute **master** for **worker** in both of these locations.

③ Specify any valid, reachable time source, such as the one provided by your DHCP server.

2. Use Butane to generate a **MachineConfig** object file, **99-worker-chrony.yaml**, containing the configuration to be delivered to the nodes:

```
$ butane 99-worker-chrony.bu -o 99-worker-chrony.yaml
```

3. Apply the configurations in one of two ways:

- If the cluster is not running yet, after you generate manifest files, add the **MachineConfig** object file to the **<installation_directory>/openshift** directory, and then continue to create the cluster.
- If the cluster is already running, apply the file:

```
$ oc apply -f ./99-worker-chrony.yaml
```

8.4.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.

NOTE

The compute node deployment steps included in this installation document are RHCOS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

You can configure RHCOS during ISO and PXE installations by using the following methods:

- Kernel arguments: You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the **APPEND** parameter to pass the arguments to

the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special **coreos.inst.*** arguments to direct the live installer, as well as standard installation boot arguments for turning standard kernel services on or off.

- Ignition configs: OpenShift Container Platform Ignition config files (***.ign**) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system after completing installation. This special Ignition config is consumed by the **coreos-installer** to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.
- **coreos-installer**: You can boot the live ISO installer to a shell prompt, which allows you to prepare the permanent system in a variety of ways before first boot. In particular, you can run the **coreos-installer** command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.

8.4.11.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your **bootstrap.ign** Ignition config file:

```
$ sha512sum <installation_directory>/bootstrap.ign
```

Example output

```
a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf011  
6e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b  
installation_directory/bootstrap.ign
```

The digests are provided to the **coreos-installer** in a later step to validate the authenticity of the Ignition config files on the cluster nodes.

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign ①
```

Example output

```
% Total % Received % Xferd Average Speed Time Time Time Current  
          Dload Upload Total Spent Left Speed  
0 0 0 0 0 0 0 0 --:--:--:--:--:--:--:-- 0{"ignition":  
{"version":"3.2.0"}, "passwd": {"users": [{"name": "core", "sshAuthorizedKeys": ["ssh-rsa...
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

4. Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

rhcoss-<version>-live.<architecture>.iso

5. Use the ISO to start the RHCOS installation. Use one of the following installation options:
 - Burn the ISO image to a disk and boot it directly.
 - Use ISO redirection by using a lights-out management (LOM) interface.
6. Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

NOTE

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the **coreos-installer** command as outlined in the following steps, instead of adding kernel arguments.

7. Run the **coreos-installer** command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device>
--ignition-hash=SHA512-<digest> ①②
```

① ② You must run the **coreos-installer** command by using **sudo**, because the **core** user does not have the required root privileges to perform the installation.

② The **--ignition-hash** option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. **<digest>** is the Ignition config file SHA512 digest obtained in a preceding step.

NOTE

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running **coreos-installer**.

The following example initializes a bootstrap node installation to the **/dev/sda** device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```
$ sudo coreos-installer install --ignition-
url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-
hash=SHA512-
a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf011
6e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.
10. Continue to create the other machines for your cluster.

IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running `ssh core@<node>. <cluster_name>`.

<**base_domain**> as a user with access to the SSH private key that is paired to the public key that you specified in your **install_config.yaml** file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

8.4.11.2. Installing RHCOS by using PXE or iPXE booting

You can use PXE or iPXE booting to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE or iPXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign ①
```

Example output

```
% Total % Received % Xferd Average Speed Time Time Current
          Dload Upload Total Spent Left Speed
0 0 0 0 0 0 0 --:--:--:--:--:-- 0{"ignition":"
{"version":"3.2.0"}, "passwd": {"users": [{"name": "core", "sshAuthorizedKeys": ["ssh-rsa...}}
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

- Obtain the RHCOS **kernel**, **initramfs** and **rootfs** files from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate **kernel**, **initramfs**, and **rootfs** artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- kernel: rhcos-<version>-live-kernel-<architecture>**
- initramfs: rhcos-<version>-live-initramfs.<architecture>.img**
- rootfs: rhcos-<version>-live-rootfs.<architecture>.img**

- Upload the **rootfs**, **kernel**, and **initramfs** files to your HTTP server.

IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

- Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.
- Configure PXE or iPXE installation for the RHCOS images and begin the installation. Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

- For PXE:

```
DEFAULT pxeboot
TIMEOUT 20
PROMPT 0
LABEL pxeboot
KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> ①
```

```
APPEND initrd=http://<HTTP_server>/rhcos-<version>-live-initramfs.
<architecture>.img coreos.live.rootfs_url=http://<HTTP_server>/rhcos-<version>-live-
rootfs.<architecture>.img coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign 2 3
```

- 1** **1** Specify the location of the live **kernel** file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.
- 2** If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named **eno1**, set **ip=eno1:dhcp**.
- 3** Specify the locations of the RHCOS files that you uploaded to your HTTP server. The **initrd** parameter value is the location of the **initramfs** file, the **coreos.live.rootfs_url** parameter value is the location of the **rootfs** file, and the **coreos.inst.ignition_url** parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the **APPEND** line to configure networking or other boot options.

NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more **console=** arguments to the **APPEND** line. For example, add **console=tty0** **console=ttyS0** to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](#)

- For iPXE:

```
kernel http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> initrd=main
coreos.live.rootfs_url=http://<HTTP_server>/rhcos-<version>-live-rootfs.
<architecture>.img coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign 1 2
initrd --name main http://<HTTP_server>/rhcos-<version>-live-initramfs.
<architecture>.img 3
boot
```

- 1** Specify the locations of the RHCOS files that you uploaded to your HTTP server. The **kernel** parameter value is the location of the **kernel** file, the **initrd=main** argument is needed for booting on UEFI systems, the **coreos.live.rootfs_url** parameter value is the location of the **rootfs** file, and the **coreos.inst.ignition_url** parameter value is the location of the bootstrap Ignition config file.
- 2** If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named **eno1**, set **ip=eno1:dhcp**.
- 3** Specify the location of the **initramfs** file that you uploaded to your HTTP server.

NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more **console=** arguments to the **kernel** line. For example, add **console=tty0** **console=ttyS0** to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](#).

7. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.
9. Continue to create the machines for your cluster.

IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running **ssh core@<node>. <cluster_name>**. **<base_domain>** as a user with access to the SSH private key that is paired to the public key that you specified in your **install_config.yaml** file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

8.4.11.3. Advanced RHCOS installation configuration

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:

- Passing kernel arguments to the live installer
- Running **coreos-installer** manually from the live system
- Embedding Ignition configs in an ISO

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

8.4.11.3.1. Using advanced networking options for PXE and ISO installations

Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:

- Pass special kernel parameters when you boot the live installer.
- Use a machine config to copy networking files to the installed system.
- Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

- See the "Advanced RHCOS installation reference" tables.
- Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

Procedure

1. Boot the ISO installer.
2. From the live system shell prompt, configure networking for the live system using available RHEL tools, such as **nmcli** or **nmtui**.
3. Run the **coreos-installer** command to install the system, adding the **--copy-network** option to copy networking configuration. For example:

```
$ coreos-installer install --copy-network \
--ignition-url=http://host/worker.ign /dev/sda
```

IMPORTANT

The **--copy-network** option only copies networking configuration found under **/etc/NetworkManager/system-connections**. In particular, it does not copy the system hostname.

4. Reboot into the installed system.

Additional resources

- See [Getting started with nmcli](#) and [Getting started with nmtui](#) in the RHEL 8 documentation for more information about the **nmcli** and **nmtui** tools.

8.4.11.3.2. Disk partitioning

The disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless the default partitioning configuration is overridden. During the RHCOS installation, the size of the root file system is increased to use the remaining available space on the target device.

There are two cases where you might want to override the default partitioning when installing RHCOS on an OpenShift Container Platform cluster node:

- Creating separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for mounting **/var** or a subdirectory of **/var**, such as **/var/lib/etcd**, on a separate partition, but not both.

IMPORTANT

Kubernetes supports only two file system partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retaining existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to **coreos-installer** that allow you to retain existing data partitions.

WARNING

The use of custom partitions could result in those partitions not being monitored by OpenShift Container Platform or alerted on. If you are overriding the default partitioning, see [Understanding OpenShift File System Monitoring \(eviction conditions\)](#) for more information about how OpenShift Container Platform monitors your host file systems.

8.4.11.3.2.1. Creating a separate **/var** partition

In general, you should use the default disk partitioning that is created during the RHCOS installation. However, there are cases where you might want to create a separate partition for a directory that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the **/var** directory or a subdirectory of **/var**. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a **/var** directory separately makes it easier to grow storage for those areas as

needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

The use of a separate partition for the `/var` directory or a subdirectory of `/var` also prevents data growth in the partitioned directory from filling up the root file system.

The following procedure sets up a separate `/var` partition by adding a machine config manifest that is wrapped into the Ignition config file for a node type during the preparation phase of an installation.

Procedure

1. On your installation host, change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ openshift-install create manifests --dir=<installation_directory>
```

2. Create a Butane config that configures the additional partition. For example, name the file `$HOME/clusterconfig/98-var-partition.bu`, change the disk device name to the name of the storage device on the `worker` systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

```
variant: openshift
version: 4.9.0
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
storage:
  disks:
    - device: /dev/<device_name> ①
      partitions:
        - label: var
          start_mib: <partition_start_offset> ②
          size_mib: <partition_size> ③
      filesystems:
        - device: /dev/disk/by-partlabel/var
          path: /var
          format: xfs
          mount_options: [defaults, prjquota] ④
          with_mount_unit: true
```

- ① The storage device name of the disk that you want to partition.
- ② When adding a data partition to the boot disk, a minimum offset value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no offset value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
- ③ The size of the data partition in mebibytes.
- ④ The `prjquota` mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate `/var` partition, you cannot use different instance types for compute nodes, if the different instance types do not have the same device name.

3. Create a manifest from the Butane config and save it to the `clusterconfig/openshift` directory. For example, run the following command:

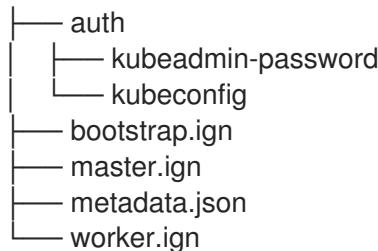

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

4. Create the Ignition config files:

```
$ openshift-install create ignition-configs --dir=<installation_directory> ①
```

- ① For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory:

The files in the `<installation_directory>/manifest` and `<installation_directory>/openshift` directories are wrapped into the Ignition config files, including the file that contains the **98-var-partition** custom **MachineConfig** object.

Next steps

- You can apply the custom disk partitioning by referencing the Ignition config files during the RHCOS installations.

8.4.11.3.2.2. Retaining existing partitions

For an ISO installation, you can add options to the `coreos-installer` command that cause the installer to maintain one or more existing partitions. For a PXE installation, you can add `coreos.inst.*` options to the **APPEND** parameter to preserve partitions.

Saved partitions might be data partitions from an existing OpenShift Container Platform system. You can identify the disk partitions you want to keep either by partition label or by number.

**NOTE**

If you save existing partitions, and those partitions do not leave enough space for RHCOS, the installation will fail without damaging the saved partitions.

Retaining existing partitions during an ISO installation

This example preserves any partition in which the partition label begins with **data (data*)**:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
--save-partlabel 'data*' /dev/sda
```

The following example illustrates running the **coreos-installer** in a way that preserves the sixth (6) partition on the disk:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
--save-partindex 6 /dev/sda
```

This example preserves partitions 5 and higher:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
--save-partindex 5- /dev/sda
```

In the previous examples where partition saving is used, **coreos-installer** recreates the partition immediately.

Retaining existing partitions during a PXE installation

This **APPEND** option preserves any partition in which the partition label begins with 'data' ('data*'):

```
coreos.inst.save_partlabel=data*
```

This **APPEND** option preserves partitions 5 and higher:

```
coreos.inst.save_partindex=5-
```

This **APPEND** option preserves partition 6:

```
coreos.inst.save_partindex=6
```

8.4.11.3.3. Identifying Ignition configs

When doing an RHCOS manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

- **Permanent install Ignition config:** Every manual RHCOS installation needs to pass one of the Ignition config files generated by **openshift-installer**, such as **bootstrap.ign**, **master.ign** and **worker.ign**, to carry out the installation.

IMPORTANT

It is not recommended to modify these Ignition config files directly. You can update the manifest files that are wrapped into the Ignition config files, as outlined in examples in the preceding sections.

For PXE installations, you pass the Ignition configs on the **APPEND** line using the **coreos.inst.ignition_url** option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the **coreos-installer** command line with the **--ignition-url**=

option. In both cases, only HTTP and HTTPS protocols are supported.

- **Live install Ignition config:** This type must be created manually and should be avoided if possible, as it is not supported by Red Hat. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before and/or after the RHCOS system installs to disk. This method should only be used for performing tasks that must be done once and not applied again later, such as with advanced partitioning that cannot be done using a machine config.
For PXE or ISO boots, you can create the Ignition config and **APPEND** the **ignition.config.url=** option to identify the location of the Ignition config. You also need to append **ignition.firstboot** **ignition.platform.id=metal** or the **ignition.config.url** option will be ignored.

8.4.11.3.3.1. Embedding a live install Ignition config in the RHCOS ISO

You can embed a live install Ignition config directly in an RHCOS ISO image. When the ISO image is booted, the embedded config will be applied automatically.

Procedure

1. Download the **coreos-installer** binary from the following image mirror page:
<https://mirror.openshift.com/pub/openshift-v4/clients/coreos-installer/latest/>.
2. Retrieve the RHCOS ISO image and the Ignition config file, and copy them into an accessible directory, such as **/mnt**:

```
# cp rhcos-<version>-live.x86_64.iso bootstrap.ign /mnt/
# chmod 644 /mnt/rhcos-<version>-live.x86_64.iso
```

3. Run the following command to embed the Ignition config into the ISO:

```
# ./coreos-installer iso ignition embed -i /mnt/bootstrap.ign \
/mnt/rhcos-<version>-live.x86_64.iso
```

You can now use that ISO to install RHCOS using the specified live install Ignition config.

IMPORTANT

Using **coreos-installer iso ignition embed** to embed a file generated by **openshift-installer**, such as **bootstrap.ign**, **master.ign** and **worker.ign**, is unsupported and not recommended.

4. To show the contents of the embedded Ignition config and direct it into a file, run:

```
# ./coreos-installer iso ignition show /mnt/rhcos-<version>-live.x86_64.iso > mybootstrap.ign
# diff -s bootstrap.ign mybootstrap.ign
```

Example output

```
Files bootstrap.ign and mybootstrap.ign are identical
```

5. To remove the Ignition config and return the ISO to its pristine state so you can reuse it, run:

```
# ./coreos-installer iso ignition remove /mnt/rhcos-<version>-live.x86_64.iso
```

You can now embed another Ignition config into the ISO or use the ISO in its pristine state.

8.4.11.3.4. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the **coreos-installer** command.

8.4.11.3.4.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

IMPORTANT

When adding networking arguments manually, you must also add the **rd.neednet=1** kernel argument to bring the network up in the initramfs.

The following table provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the **ip=**, **nameserver=**, and **bond=** kernel arguments.

NOTE

Ordering is important when adding the kernel arguments: **ip=**, **nameserver=**, and then **bond=**.

The networking options are passed to the **dracut** tool during system boot. For more information about the networking options supported by **dracut**, see the **dracut.cmdline** manual page.

Table 8.43. Networking and bonding options for ISO installations

Description	Examples
<p>To configure an IP address, either use DHCP (ip=dhcp) or set an individual static IP address (ip=<host_ip>). If setting a static IP, you must then identify the DNS server IP address (nameserver=<dns_ip>) on each node. This example sets:</p> <ul style="list-style-type: none"> • The node's IP address to 10.10.10.2 • The gateway address to 10.10.10.254 • The netmask to 255.255.255.0 • The hostname to core0.example.com • The DNS server address to 4.4.4.41 • The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically. <p> NOTE</p> <p>When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none nameserver=4.4.4.41</pre>
<p>Specify multiple network interfaces by specifying multiple ip= entries.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none</pre>
<p>Optional: You can configure routes to additional networks by setting an rd.route= value.</p> <p>If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.</p>	<p>To configure the default gateway:</p> <pre>ip=:10.10.10.254:::</pre> <p>To configure the route for the additional network:</p> <pre>rd.route=20.20.20.0/24:20.20.20.254:enp2s0</pre>

Description	Examples
<p>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the enp1s0 interface has a static networking configuration and DHCP is disabled for enp2s0, which is not used.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ip=::::core0.example.com:enp2s0:none</pre>
<p>You can combine DHCP and static IP configurations on systems with multiple network interfaces.</p>	<pre>ip=enp1s0:dhcp ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none</pre>
<p>Optional: You can configure VLANs on individual interfaces by using the vlan= parameter.</p>	<p>To configure a VLAN on a network interface and use a static IP address:</p> <pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none vlan=enp2s0.100:enp2s0</pre> <p>To configure a VLAN on a network interface and to use DHCP:</p> <pre>ip=enp2s0.100:dhcp vlan=enp2s0.100:enp2s0</pre>
<p>You can provide multiple DNS servers by adding a nameserver= entry for each server.</p>	<pre>nameserver=1.1.1.1 nameserver=8.8.8.8</pre>
<p>Optional: Bonding multiple network interfaces to a single interface is supported using the bond= option. In these two examples:</p> <ul style="list-style-type: none"> The syntax for configuring a bonded interface is: bond=name[:network_interfaces] [:options] <i>name</i> is the bonding device name (bond0), <i>network_interfaces</i> represents a comma-separated list of physical (ethernet) interfaces (em1,em2), and <i>options</i> is a comma-separated list of bonding options. Enter modinfo bonding to see available options. When you create a bonded interface using bond=, you must specify how the IP address is assigned and other information for the bonded interface. 	<p>To configure the bonded interface to use DHCP, set the bond's IP address to dhcp. For example:</p> <pre>bond=bond0:em1,em2:mode=active-backup ip=bond0:dhcp</pre> <p>To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:</p> <pre>bond=bond0:em1,em2:mode=active-backup ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none</pre>

Description	Examples
Optional: You can configure VLANs on bonded interfaces by using the vlan= parameter.	To configure the bonded interface with a VLAN and to use DHCP: ip=bond0.100:dhcp bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0
	To configure the bonded interface with a VLAN and to use a static IP address: ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:bond0.100:none bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0

8.4.11.3.4.2. coreos-installer options for ISO installations

You can install RHCOS by running **coreos-installer install <options> <device>** at the command prompt, after booting into the RHCOS live environment from an ISO image.

The following table shows the subcommands, options, and arguments you can pass to the **coreos-installer** command.

Table 8.44. coreos-installer subcommands, command-line options, and arguments

coreos-installer install subcommand	
<i>Subcommand</i>	<i>Description</i>
\$ coreos-installer install <options> <device>	Embed an Ignition config in an ISO image.
coreos-installer install subcommand options	
<i>Option</i>	<i>Description</i>
-u, --image-url <url>	Specify the image URL manually.
-f, --image-file <path>	Specify a local image file manually. Used for debugging.
-i, --ignition-file <path>	Embed an Ignition config from a file.
-l, --ignition-url <URL>	Embed an Ignition config from a URL.
--ignition-hash <digest>	Digest type-value of the Ignition config.

-p, --platform <name>	Override the Ignition platform ID for the installed system.
--append-karg <arg>...	Append a default kernel argument to the installed system.
--delete-karg <arg>...	Delete a default kernel argument from the installed system.
-n, --copy-network	Copy the network configuration from the install environment. +
	<p>IMPORTANT</p> <p>The --copy-network option only copies networking configuration found under /etc/NetworkManager/system-connections. In particular, it does not copy the system hostname.</p>
--network-dir <path>	For use with -n . Default is /etc/NetworkManager/system-connections/ .
--save-partlabel <lx>..	Save partitions with this label glob.
--save-partindex <id>...	Save partitions with this number or range.
--insecure	Skip signature verification.
--insecure-ignition	Allow Ignition URL without HTTPS or hash.
--architecture <name>	Target CPU architecture. Default is x86_64 .
--preserve-on-error	Do not clear partition table on error.
-h, --help	Print help information.
coreos-install install subcommand argument	
<i>Argument</i>	<i>Description</i>
<device>	The destination device.
coreos-installer ISO Ignition subcommands	
<i>Subcommand</i>	<i>Description</i>

<pre>\$ coreos-installer iso ignition embed <options> --ignition-file <file_path> <ISO_image></pre>	Embed an Ignition config in an ISO image.
coreos-installer iso ignition show <options> <ISO_image>	Show the embedded Ignition config from an ISO image.
coreos-installer iso ignition remove <options> <ISO_image>	Remove the embedded Ignition config from an ISO image.

coreos-installer ISO Ignition subcommand options

<i>Option</i>	<i>Description</i>
-f, --force	Overwrite an existing Ignition config.
-i, --ignition-file <path>	The Ignition config to be used. Default is stdin .
-o, --output <path>	Write the ISO to a new output file.
-h, --help	Print help information.

coreos-installer PXE Ignition subcommands

<i>Subcommand</i>	<i>Description</i>
Note that not all of these options are accepted by all subcommands.	
coreos-installer pxe ignition wrap <options>	Wrap an Ignition config in an image.
coreos-installer pxe ignition unwrap <options> <image_name>	Show the wrapped Ignition config in an image.

coreos-installer PXE Ignition subcommand options

<i>Option</i>	<i>Description</i>
Note that not all of these options are accepted by all subcommands.	
-i, --ignition-file <path>	The Ignition config to be used. Default is stdin .
-o, --output <path>	Write the ISO to a new output file.
-h, --help	Print help information.

8.4.11.3.4.3. **coreos.inst** boot options for ISO or PXE installations

You can automatically invoke **coreos-installer** options at boot time by passing **coreos.inst** boot arguments to the RHCOS live installer. These are provided in addition to the standard boot arguments.

- For ISO installations, the **coreos.inst** options can be added by interrupting the automatic boot at the bootloader menu. You can interrupt the automatic boot by pressing **TAB** while the **RHEL CoreOS (Live)** menu option is highlighted.
- For PXE or iPXE installations, the **coreos.inst** options must be added to the **APPEND** line before the RHCOS live installer is booted.

The following table shows the RHCOS live installer **coreos.inst** boot options for ISO and PXE installations.

Table 8.45. coreos.inst boot options

Argument	Description
coreos.inst.install_dev	Required. The block device on the system to install to. It is recommended to use the full path, such as /dev/sda , although sda is allowed.
coreos.inst.ignition_url	Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded. Only HTTP and HTTPS protocols are supported.
coreos.inst.save_partlabel	Optional: Comma-separated labels of partitions to preserve during the install. Glob-style wildcards are permitted. The specified partitions do not need to exist.
coreos.inst.save_partindex	Optional: Comma-separated indexes of partitions to preserve during the install. Ranges m-n are permitted, and either m or n can be omitted. The specified partitions do not need to exist.
coreos.inst.insecure	Optional: Permits the OS image that is specified by coreos.inst.image_url to be unsigned.

Argument	Description
coreos.inst.image_url	<p>Optional: Download and install the specified RHCOS image.</p> <ul style="list-style-type: none"> ● This argument should not be used in production environments and is intended for debugging purposes only. ● While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install. ● If you are using coreos.inst.image_url, you must also use coreos.inst.insecure. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform. ● Only HTTP and HTTPS protocols are supported.
coreos.inst.skip_reboot	<p>Optional: The system will not reboot after installing. After the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only.</p>
coreos.inst.platform_id	<p>Optional: The Ignition platform ID of the platform the RHCOS image is being installed on. Default is metal. This option determines whether or not to request an Ignition config from the cloud provider, such as VMware. For example: coreos.inst.platform_id=vmware.</p>
ignition.config.url	<p>Optional: The URL of the Ignition config for the live boot. For example, this can be used to customize how coreos-installer is invoked, or to run code before or after the installation. This is different from coreos.inst.ignition_url, which is the Ignition config for the installed system.</p>

8.4.11.4. Enabling multipathing with kernel arguments on RHCOS

RHCOS supports multipathing on the primary disk, allowing stronger resilience to hardware failure to achieve higher host availability.

You can enable multipathing at installation time for nodes that were provisioned in OpenShift Container Platform 4.8 or later. While post-installation support is available by activating multipathing via the machine config, enabling multipathing during installation is recommended.

In setups where any I/O to non-optimized paths results in I/O system errors, you must enable multipathing at installation time.

IMPORTANT

On IBM Z and LinuxONE, you can enable multipathing only if you configured your cluster for it during installation. For more information, see "Installing RHCOS and starting the OpenShift Container Platform bootstrap process" in *Installing a cluster with z/VM on IBM Z and LinuxONE*.

The following procedure enables multipath at installation time and appends kernel arguments to the **coreos-installer install** command so that the installed system itself will use multipath beginning from the first boot.

Prerequisites

- You have a running OpenShift Container Platform cluster that uses version 4.8 or later.
- You are logged in to the cluster as a user with administrative privileges.

Procedure

1. To enable multipath and start the **multipathd** daemon, run the following command:

```
$ mpathconf --enable && systemctl start multipathd.service
```

- Optional: If booting the PXE or ISO, you can instead enable multipath by adding **rd.multipath=default** from the kernel command line.

2. Append the kernel arguments by invoking the **coreos-installer** program:

- If there is only one multipath device connected to the machine, it should be available at path **/dev/mapper/mpatha**. For example:

```
$ coreos-installer install /dev/mapper/mpatha \ ①
--append-karg rd.multipath=default \
--append-karg root=/dev/disk/by-label/dm-mpath-root
```

① Indicates the path of the single multipathed device.

- If there are multiple multipath devices connected to the machine, or to be more explicit, instead of using **/dev/mapper/mpatha**, it is recommended to use the World Wide Name (WWN) symlink available in **/dev/disk/by-id**. For example:

```
$ coreos-installer install /dev/disk/by-id/wwn-<wwn_ID> \ ①
--append-karg rd.multipath=default \
--append-karg root=/dev/disk/by-label/dm-mpath-root
```

① Indicates the WWN ID of the target multipathed device. For example, **0xx194e957fcedb4841**.

This symlink can also be used as the **coreos.inst.install_dev** kernel argument when using special **coreos.inst.*** arguments to direct the live installer. For more information, see "Installing RHCOS and starting the OpenShift Container Platform bootstrap process".

- Check that the kernel arguments worked by going to one of the worker nodes and listing the kernel command line arguments (in **/proc/cmdline** on the host):

```
$ oc debug node/ip-10-0-141-105.ec2.internal
```

Example output

```
Starting pod/ip-10-0-141-105ec2internal-debug ...
To use host binaries, run `chroot /host`

sh-4.2# cat /host/proc/cmdline
...
rd.multipath=default root=/dev/disk/by-label/dm-mpath-root
...
sh-4.2# exit
```

You should see the added kernel arguments.

8.4.11.5. Updating the bootloader using bootupd

To update the bootloader by using **bootupd**, you must either install **bootupd** on RHCOS machines manually or provide a machine config with the enabled **systemd** unit. Unlike **grubby** or other bootloader tools, **bootupd** does not manage kernel space configuration such as passing kernel arguments.

After you have installed **bootupd**, you can manage it remotely from the OpenShift Container Platform cluster.

NOTE

It is recommended that you use **bootupd** only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

Manual install method

You can manually install **bootupd** by using the **bootctl** command-line tool.

- Inspect the system status:

```
# bootupctl status
```

Example output

```
Component EFI
Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
Update: At latest version
```

- RHCOS images created without **bootupd** installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

```
# bootupctl adopt-and-update
```

Example output

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

```
# bootupctl update
```

Example output

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

Machine config method

Another way to enable **bootupd** is by providing a machine config.

- Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

Example output

```
variant: rhcos
version: 1.1.0
systemd:
  units:
    - name: custom-bootupd-auto.service
      enabled: true
      contents: |
        [Unit]
        Description=Bootupd automatic update

        [Service]
        ExecStart=/usr/bin/bootupctl update
        RemainAfterExit=yes

        [Install]
        WantedBy=multi-user.target
```

8.4.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.

- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

Procedure

1. Monitor the bootstrap process:

```
$ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \ ①
--log-level=info ②
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.22.1 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

IMPORTANT

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

Additional resources

- See [Monitoring installation progress](#) for more information about monitoring the installation logs and retrieving diagnostic data if installation issues arise.

8.4.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- ① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

8.4.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.22.1
master-1	Ready	master	63m	v1.22.1
master-2	Ready	master	64m	v1.22.1

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-8b2br	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
csr-8vnps	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
...			

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

- If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approvers** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	Pending
csr-c571v	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	Pending
...			

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{{if not .status}}}{{.metadata.name}}\n{{end}}{{end}}' | xargs oc adm certificate approve
```

- After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	73m	v1.22.1
master-1	Ready	master	73m	v1.22.1
master-2	Ready	master	74m	v1.22.1
worker-0	Ready	worker	11m	v1.22.1
worker-1	Ready	worker	11m	v1.22.1

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

8.4.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

- Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.9.0	True	False	False 19m
baremetal	4.9.0	True	False	False 37m
cloud-credential	4.9.0	True	False	False 40m
cluster-autoscaler	4.9.0	True	False	False 37m
config-operator	4.9.0	True	False	False 38m
console	4.9.0	True	False	False 26m
csi-snapshot-controller	4.9.0	True	False	False 37m
dns	4.9.0	True	False	False 37m
etcd	4.9.0	True	False	False 36m
image-registry	4.9.0	True	False	False 31m
ingress	4.9.0	True	False	False 30m
insights	4.9.0	True	False	False 31m
kube-apiserver	4.9.0	True	False	False 26m
kube-controller-manager	4.9.0	True	False	False 36m
kube-scheduler	4.9.0	True	False	False 36m
kube-storage-version-migrator	4.9.0	True	False	False 37m
machine-api	4.9.0	True	False	False 29m
machine approver	4.9.0	True	False	False 37m
machine-config	4.9.0	True	False	False 36m
marketplace	4.9.0	True	False	False 37m
monitoring	4.9.0	True	False	False 29m
network	4.9.0	True	False	False 38m
node-tuning	4.9.0	True	False	False 37m
openshift-apiserver	4.9.0	True	False	False 32m
openshift-controller-manager	4.9.0	True	False	False 30m
openshift-samples	4.9.0	True	False	False 32m
operator-lifecycle-manager	4.9.0	True	False	False 37m
operator-lifecycle-manager-catalog	4.9.0	True	False	False 37m
operator-lifecycle-manager-packageserver	4.9.0	True	False	False 32m
service-ca	4.9.0	True	False	False 38m
storage	4.9.0	True	False	False 37m

2. Configure the Operators that are not available.

Additional resources

- See [Gathering logs from a failed installation](#) for details about gathering data in the event of a failed OpenShift Container Platform installation.
- See [Troubleshooting Operator issues](#) for steps to check Operator pod health across the cluster and gather Operator logs for diagnosis.

8.4.15.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding **disableAllDefaultSources: true** to the **OperatorHub** object:

```
$ oc patch OperatorHub cluster --type json \
-p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
```

TIP

Alternatively, you can use the web console to manage catalog sources. From the **Administration → Cluster Settings → Global Configuration → OperatorHub** page, click the **Sources** tab, where you can create, delete, disable, and enable individual sources.

8.4.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

8.4.15.2.1. Changing the image registry's management state

To start the image registry, you must change the Image Registry Operator configuration's **managementState** from **Removed** to **Managed**.

Procedure

- Change **managementState** Image Registry Operator configuration from **Removed** to **Managed**. For example:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"managementState": "Managed"}}'
```

8.4.15.2.2. Configuring registry storage for bare metal and other manual installations

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster that uses manually-provisioned Red Hat Enterprise Linux CoreOS (RHCOS) nodes, such as bare metal.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Container Storage.

IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

NOTE

When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry
```

NOTE

If the storage type is **emptyDIR**, the replica number cannot be greater than **1**.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

Example output

```
storage:
  pvc:
    claim:
```

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

- Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

- Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

```
$ oc edit configs.imageregistry/cluster
```

Then, change the line

```
managementState: Removed
```

```

8.4.15.2.3. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage":{"emptyDir":{}}}}'
```

WARNING

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

8.4.15.2.4. Configuring block registry storage

To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

IMPORTANT

Block storage volumes are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only one (1) replica:

```
$ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy":"Recreate","replicas":1}}'
```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.
3. Edit the registry configuration so that it references the correct PVC.

8.4.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME	VERSION	AVAILABLE	PROGRESSING	DEGRADED
SINCE				
authentication	4.9.0	True	False	False 19m
baremetal	4.9.0	True	False	False 37m
cloud-credential	4.9.0	True	False	False 40m
cluster-autoscaler	4.9.0	True	False	False 37m
config-operator	4.9.0	True	False	False 38m
console	4.9.0	True	False	False 26m
csi-snapshot-controller	4.9.0	True	False	False 37m
dns	4.9.0	True	False	False 37m
etcd	4.9.0	True	False	False 36m

image-registry	4.9.0	True	False	False	31m
ingress	4.9.0	True	False	False	30m
insights	4.9.0	True	False	False	31m
kube-apiserver	4.9.0	True	False	False	26m
kube-controller-manager	4.9.0	True	False	False	36m
kube-scheduler	4.9.0	True	False	False	36m
kube-storage-version-migrator	4.9.0	True	False	False	37m
machine-api	4.9.0	True	False	False	29m
machine approver	4.9.0	True	False	False	37m
machine-config	4.9.0	True	False	False	36m
marketplace	4.9.0	True	False	False	37m
monitoring	4.9.0	True	False	False	29m
network	4.9.0	True	False	False	38m
node-tuning	4.9.0	True	False	False	37m
openshift-apiserver	4.9.0	True	False	False	32m
openshift-controller-manager	4.9.0	True	False	False	30m
openshift-samples	4.9.0	True	False	False	32m
operator-lifecycle-manager	4.9.0	True	False	False	37m
operator-lifecycle-manager-catalog	4.9.0	True	False	False	37m
operator-lifecycle-manager-packageserver	4.9.0	True	False	False	32m
service-ca	4.9.0	True	False	False	38m
storage	4.9.0	True	False	False	37m

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete ①
```

- ① For <installation_directory>, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.

- a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

Example output

NAMESPACE	NAME	READY	STATUS
RESTARTS	AGE		
openshift-apiserver-operator	openshift-apiserver-operator-85cb746d55-zqhs8	1/1	
Running 1	9m		
openshift-apiserver	apiserver-67b9g	1/1	Running 0
3m			
openshift-apiserver	apiserver-ljcmx	1/1	Running 0
1m			
openshift-apiserver	apiserver-z25h4	1/1	Running 0
2m			
openshift-authentication-operator	authentication-operator-69d5d8bf84-vh2n8	1/1	
Running 0	5m		
...			

- b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> ①
```

- ① Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.
See "Enabling multipathing with kernel arguments on RHCOS" in the *Post-installation machine configuration tasks* documentation for more information.
4. Register your cluster on the [Cluster registration](#) page.

8.4.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by [configuring additional trust stores](#).
- If necessary, you can [opt out of remote health reporting](#).

CHAPTER 9. INSTALLING ON A SINGLE NODE

9.1. PREPARING TO INSTALL ON A SINGLE NODE

9.1.1. About installing on a single node

An installation of OpenShift Container Platform on a single node is a specialized installation. The primary use case is for edge computing workloads, including small physical footprints, intermittent connectivity, portable clouds, and 5G radio access networks (RAN) close to a base station. An installation on a single node supports autonomous workloads.

The major trade off with an installation on a single node is the lack of high availability.

9.1.2. Requirements for installing on a single node

Installing OpenShift Container Platform on a single node alleviates some of the requirements of high availability and large scale clusters. However, you must address the following requirements:

- **Administration node:** You must have an administration node or laptop to access [Install OpenShift with the Assisted Installer](#), to specify the cluster name, to create the USB boot drive, and to monitor the installation.
- **Production-grade server:** Installing OpenShift Container Platform on a single node requires a server with sufficient resources to run OpenShift Container Platform services and a production workload.

Table 9.1. Hardware requirements

Profile	vCPU	Memory	Storage
Minimum	8 vCPU cores	32GB of RAM	120GB

NOTE

One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio:

$$(\text{threads per core} \times \text{cores}) \times \text{sockets} = \text{vCPUs}$$

The server must have a Baseboard Management Controller (BMC) when booting with virtual media.

- **Networking:** The server must have access to the internet or access to a local registry if it is not connected to a routable network. The server must have a DHCP reservation or a static IP address for the Kubernetes API, Ingress route, and cluster node domain names. You must configure the DNS to resolve the IP address to each of the following fully qualified domain names (FQDN):

Table 9.2. Required DNS records

Usage	FQDN	Description
Kubernetes API	<code>api.<cluster_name>. <base_domain></code>	Add a DNS A/AAAA or CNAME record. This record must be resolvable by clients external to the cluster.
Ingress route	<code>*.apps.<cluster_name>. <base_domain></code>	Add a wildcard DNS A/AAAA or CNAME record that targets the node. This record must be resolvable by clients external to the cluster.
Cluster node	<code><hostname>. <cluster_name>. <base_domain></code>	Add a DNS A/AAAA or CNAME record and DNS PTR record to identify the node.

Without persistent IP addresses, communications between the **apiserver** and **etcd** might fail.

9.2. INSTALLING ON A SINGLE NODE

9.2.1. Generate the discovery ISO

Installing OpenShift Container Platform on a single node requires a discovery ISO, which the Assisted Installer (AI) generates with the cluster name, base domain, Secure Shell (SSH) public key, and pull secret.

Procedure

1. On the administration node, open a browser and navigate to [Install OpenShift with the Assisted Installer](#).
2. Click **Create New Cluster** to create a new cluster.
3. In the **Cluster Name** field, enter a name for the cluster.
4. In the **Base Domain** field, enter a base domain. For example:

example.com

All DNS records must be subdomains of this base domain and include the cluster name. You cannot change the base domain after cluster installation. For example:

<cluster-name>.example.com

5. Select "I want to install single node OpenShift (SNO)".
6. Read the limitations for installing OpenShift Container Platform on a single node.

7. Select "I understand, accept, and agree to the limitations associated with using Single Node OpenShift".
8. Select the OpenShift Container Platform version.
9. Click **Next**.
10. Click **Generate Discovery ISO**.
11. Select **Full ISO** to boot with a USB drive or PXE. Select **Minimal ISO** to boot with virtual media.
12. Add the Secure Shell public key of the administration node to the **Public key** field.
13. Click **Generate Discovery ISO**.
14. Download the discovery ISO.
15. Make a note of the discovery ISO URL for installing with virtual media.

9.2.2. Installing with USB media

Installing with USB media involves creating a bootable USB drive with the discovery ISO on the administration node. Booting the server with the USB drive prepares the node for a single node installation.

Procedure

1. On the administration node, insert a USB drive into a USB port.
2. Create a bootable USB drive:

```
# dd if=<path-to-iso> of=<path/to/usb> status=progress
```

For example:

```
# dd if=discovery_image_sno.iso of=/dev/sdb status=progress
```

After the ISO is copied to the USB drive, you can use the USB drive to install OpenShift Container Platform.

3. On the server, insert the USB drive into a USB port.
4. Reboot the server and enter the BIOS settings upon reboot.
5. Change boot drive order to make the USB drive boot first.
6. Save and exit the BIOS settings. The server will boot with the discovery image.
7. On the administration node, return to the browser and refresh the page. If necessary, reload the [Install OpenShift with the Assisted Installer](#) page and select the cluster name.
8. Click **Next** until you reach step 3.
9. Select a subnet from the available subnets.

10. Keep **Use the same host discovery SSH key** checked. You can change the SSH public key, if necessary.
11. Click **Next** to step 4.
12. Click **Install cluster**.
13. Monitor the installation's progress. Watch the cluster events. After the installation process finishes writing the discovery image to the server's drive, the server will reboot. Remove the USB drive and reset the BIOS to boot to the server's local media rather than the USB drive.

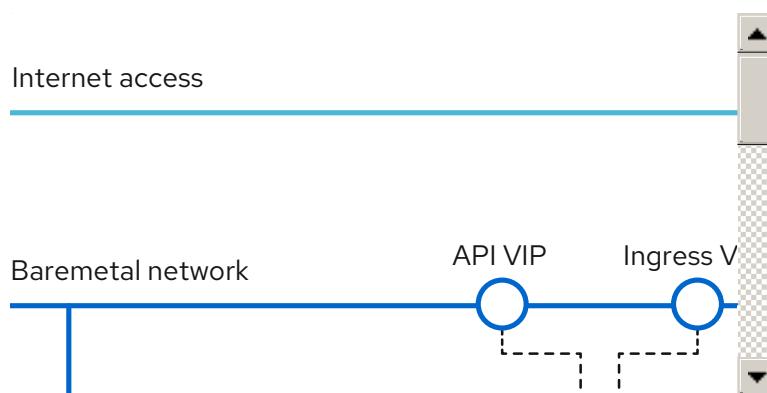

The server will reboot several times, deploying a control plane followed by a worker.

CHAPTER 10. DEPLOYING INSTALLER-PROVISIONED CLUSTERS ON BARE METAL

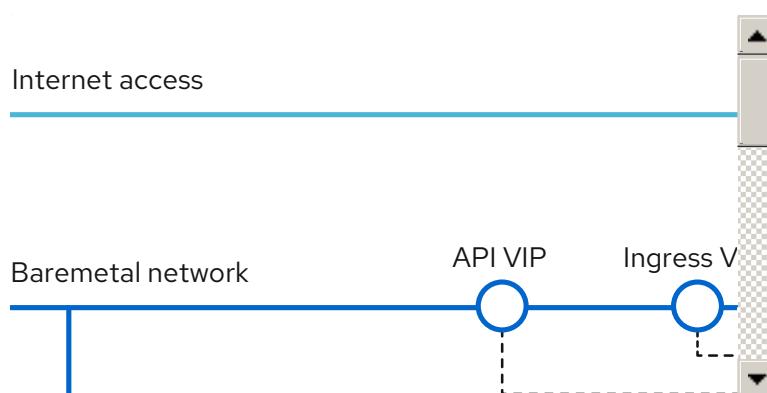

10.1. OVERVIEW

Installer-provisioned installation provides support for installing OpenShift Container Platform on bare metal nodes. This guide provides a methodology to achieving a successful installation.

During installer-provisioned installation on bare metal, the installer on the bare metal node labeled as **provisioner** creates a bootstrap virtual machine (VM). The role of the bootstrap VM is to assist in the process of deploying an OpenShift Container Platform cluster. The bootstrap VM connects to the **baremetal** network and to the **provisioning** network, if present, via the network bridges.

When the installation of OpenShift control plane nodes is complete and fully operational, the installer destroys the bootstrap VM automatically and moves the virtual IP addresses (VIPs) to the control plane nodes.

IMPORTANT

The **provisioning** network is optional, but it is required for PXE booting. If you deploy without a **provisioning** network, you must use a virtual media BMC addressing option such as **redfish-virtualmedia** or **idrac-virtualmedia**.

10.2. PREREQUISITES

Installer-provisioned installation of OpenShift Container Platform requires:

1. One provisioner node with Red Hat Enterprise Linux (RHEL) 8.x installed.
2. Three control plane nodes.

3. Baseboard Management Controller (BMC) access to each node.
4. At least one network:
 - a. One required routable network
 - b. One optional network for provisioning nodes; and,
 - c. One optional management network.

Before starting an installer-provisioned installation of OpenShift Container Platform, ensure the hardware environment meets the following requirements.

10.2.1. Node requirements

Installer-provisioned installation involves a number of hardware node requirements:

- **CPU architecture:** All nodes must use **x86_64** CPU architecture.
- **Similar nodes:** Red Hat recommends nodes have an identical configuration per role. That is, Red Hat recommends nodes be the same brand and model with the same CPU, memory, and storage configuration.
- **Baseboard Management Controller:** The **provisioner** node must be able to access the baseboard management controller (BMC) of each OpenShift Container Platform cluster node. You may use IPMI, Redfish, or a proprietary protocol.
- **Latest generation:** Nodes must be of the most recent generation. Installer-provisioned installation relies on BMC protocols, which must be compatible across nodes. Additionally, RHEL 8 ships with the most recent drivers for RAID controllers. Ensure that the nodes are recent enough to support RHEL 8 for the **provisioner** node and RHCOS 8 for the control plane and worker nodes.
- **Registry node:** (Optional) If setting up a disconnected mirrored registry, it is recommended the registry reside in its own node.
- **Provisioner node:** Installer-provisioned installation requires one **provisioner** node.
- **Control plane:** Installer-provisioned installation requires three control plane nodes for high availability. You can deploy an OpenShift Container Platform cluster with only three control plane nodes, making the control plane nodes schedulable as worker nodes. Smaller clusters are more resource efficient for administrators and developers during development, production, and testing.
- **Worker nodes:** While not required, a typical production cluster has two or more worker nodes.

IMPORTANT

Do not deploy a cluster with only one worker node, because the cluster will deploy with routers and ingress traffic in a degraded state.

- **Network interfaces:** Each node must have at least one 10GB network interface for the routable **baremetal** network. Each node must have one 10GB network interface for a **provisioning** network when using the **provisioning** network for deployment. Using the **provisioning** network is the default configuration. Network interface names must follow the same naming convention

across all nodes. For example, the first NIC name on a node, such as **eth0** or **eno1**, must be the same name on all of the other nodes. The same principle applies to the remaining NICs on each node.

- **Unified Extensible Firmware Interface (UEFI):** Installer-provisioned installation requires UEFI boot on all OpenShift Container Platform nodes when using IPv6 addressing on the **provisioning** network. In addition, UEFI Device PXE Settings must be set to use the IPv6 protocol on the **provisioning** network NIC, but omitting the **provisioning** network removes this requirement.
- **Secure Boot:** Many production scenarios require nodes with Secure Boot enabled to verify the node only boots with trusted software, such as UEFI firmware drivers, EFI applications, and the operating system. You may deploy with Secure Boot manually or managed.
 1. **Manually:** To deploy an OpenShift Container Platform cluster with Secure Boot manually, you must enable UEFI boot mode and Secure Boot on each control plane node and each worker node. Red Hat supports Secure Boot with manually enabled UEFI and Secure Boot only when installer-provisioned installations use Redfish virtual media. See "Configuring nodes for Secure Boot manually" in the "Configuring nodes" section for additional details.
 2. **Managed:** To deploy an OpenShift Container Platform cluster with managed Secure Boot, you must set the **bootMode** value to **UEFISecureBoot** in the **install-config.yaml** file. Red Hat only supports installer-provisioned installation with managed Secure Boot on 10th generation HPE hardware and 13th generation Dell hardware running firmware version **2.75.75.75** or greater. Deploying with managed Secure Boot does not require Redfish virtual media. See "Configuring managed Secure Boot" in the "Setting up the environment for an OpenShift installation" section for details.

NOTE

Red Hat does not support Secure Boot with self-generated keys.

10.2.2. Firmware requirements for installing with virtual media

The installer for installer-provisioned OpenShift Container Platform clusters validates the hardware and firmware compatibility with Redfish virtual media. The following table lists supported firmware for installer-provisioned OpenShift Container Platform clusters deployed with Redfish virtual media.

Table 10.1. Firmware compatibility for Redfish virtual media

Hardware	Model	Management	Firmware Versions
HP	10th Generation	iLO5	N/A
	9th Generation	iLO4	N/A
Dell	14th Generation	iDRAC 9	v4.20.20.20 - 04.40.00.00
	13th Generation	iDRAC 8	v2.75.75.75+

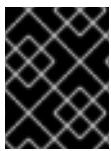

NOTE

See the hardware documentation for the nodes or contact the hardware vendor for information on updating the firmware.

There are no known firmware limitations for HP servers.

For Dell servers, ensure the OpenShift Container Platform cluster nodes have AutoAttach Enabled through the iDRAC console. The menu path is: **Configuration → Virtual Media → Attach Mode → AutoAttach**. With iDRAC 9 firmware version **04.40.00.00**, the Virtual Console plug-in defaults to **eHTML5**, which causes problems with the **InsertVirtualMedia** workflow. Set the plug-in to **HTML5** to avoid this issue. The menu path is: **Configuration → Virtual console → Plug-in Type → HTML5**.

IMPORTANT

The installer will not initiate installation on a node if the node firmware is below the foregoing versions when installing with virtual media.

10.2.3. Network requirements

Installer-provisioned installation of OpenShift Container Platform involves several network requirements. First, installer-provisioned installation involves an optional non-routable **provisioning** network for provisioning the operating system on each bare metal node. Second, installer-provisioned installation involves a routable **baremetal** network.

Configuring NICs

OpenShift Container Platform deploys with two networks:

- **provisioning**: The **provisioning** network is an optional non-routable network used for provisioning the underlying operating system on each node that is a part of the OpenShift Container Platform cluster. The network interface for the **provisioning** network on each cluster node must have the BIOS or UEFI configured to PXE boot.
The **provisioningNetworkInterface** configuration setting specifies the **provisioning** network NIC name on the control plane nodes, which must be identical on the control plane nodes. The **bootMACAddress** configuration setting provides a means to specify a particular NIC on each node for the **provisioning** network.

The **provisioning** network is optional, but it is required for PXE booting. If you deploy without a **provisioning** network, you must use a virtual media BMC addressing option such as **redfish-virtualmedia** or **idrac-virtualmedia**.

- **baremetal**: The **baremetal** network is a routable network. You can use any NIC to interface with the **baremetal** network provided the NIC is not configured to use the **provisioning** network.

IMPORTANT

When using a VLAN, each NIC must be on a separate VLAN corresponding to the appropriate network.

Configuring the DNS server

Clients access the OpenShift Container Platform cluster nodes over the **baremetal** network. A network administrator must configure a subdomain or subzone where the canonical name extension is the cluster name.

`<cluster_name>.<domain>`

For example:

`test-cluster.example.com`

OpenShift Container Platform includes functionality that uses cluster membership information to generate A/AAAA records. This resolves the node names to their IP addresses. After the nodes are registered with the API, the cluster can disperse node information without using CoreDNS-mDNS. This eliminates the network traffic associated with multicast DNS.

IMPORTANT

You must create a DNS entry for the `api.<cluster_name>.<domain>` domain name on the external DNS because removing CoreDNS causes the local entry to disappear. Failure to create a DNS record for the `api.<cluster_name>.<domain>` domain name in the external DNS server precludes worker nodes from joining the cluster.

Dynamic Host Configuration Protocol (DHCP) requirements

By default, installer-provisioned installation deploys `ironic-dnsmasq` with DHCP enabled for the **provisioning** network. No other DHCP servers should be running on the **provisioning** network when the **provisioningNetwork** configuration setting is set to **managed**, which is the default value. If you have a DHCP server running on the **provisioning** network, you must set the **provisioningNetwork** configuration setting to **unmanaged** in the `install-config.yaml` file.

Network administrators must reserve IP addresses for each node in the OpenShift Container Platform cluster for the **baremetal** network on an external DHCP server.

Reserving IP addresses for nodes with the DHCP server

For the **baremetal** network, a network administrator must reserve a number of IP addresses, including:

1. Two virtual IP addresses.
 - One IP address for the API endpoint
 - One IP address for the wildcard ingress endpoint
2. One IP address for the provisioner node.
3. One IP address for each control plane (master) node.
4. One IP address for each worker node, if applicable.

RESERVING IP ADDRESSES SO THEY BECOME STATIC IP ADDRESSES

Some administrators prefer to use static IP addresses so that each node's IP address remains constant in the absence of a DHCP server. To use static IP addresses in the OpenShift Container Platform cluster, reserve the IP addresses with an infinite lease. During deployment, the installer will reconfigure the NICs from DHCP assigned addresses to static IP addresses. NICs with DHCP leases that are not infinite will remain configured to use DHCP.

NETWORKING BETWEEN EXTERNAL LOAD BALANCERS AND CONTROL PLANE NODES

External load balancing services and the control plane nodes must run on the same L2 network, and on the same VLAN when using VLANs to route traffic between the load balancing services and the control plane nodes.

The following table provides an exemplary embodiment of fully qualified domain names. The API and Nameserver addresses begin with canonical name extensions. The hostnames of the control plane and worker nodes are exemplary, so you can use any host naming convention you prefer.

Usage	Host Name	IP
API	<code>api.<cluster_name>.<domain></code>	<ip>
Ingress LB (apps)	<code>*.apps.<cluster_name>.<domain></code>	<ip>
Provisioner node	<code>provisioner.<cluster_name>.<domain></code>	<ip>
Master-0	<code>openshift-master-0.<cluster_name>.<domain></code>	<ip>
Master-1	<code>openshift-master-1.<cluster_name>.<domain></code>	<ip>
Master-2	<code>openshift-master-2.<cluster_name>.<domain></code>	<ip>
Worker-0	<code>openshift-worker-0.<cluster_name>.<domain></code>	<ip>
Worker-1	<code>openshift-worker-1.<cluster_name>.<domain></code>	<ip>
Worker-n	<code>openshift-worker-n.<cluster_name>.<domain></code>	<ip>

Network Time Protocol (NTP)

Each OpenShift Container Platform node in the cluster must have access to an NTP server. OpenShift Container Platform nodes use NTP to synchronize their clocks. For example, cluster nodes use SSL certificates that require validation, which might fail if the date and time between the nodes are not in sync.

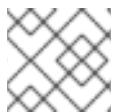

IMPORTANT

Define a consistent clock date and time format in each cluster node's BIOS settings, or installation might fail.

You may reconfigure the control plane nodes to act as NTP servers on disconnected clusters, and reconfigure worker nodes to retrieve time from the control plane nodes.

State-driven network configuration requirements (Technology Preview)

OpenShift Container Platform supports additional post-installation state-driven network configuration on the secondary network interfaces of cluster nodes using **kubernetes-nmstate**. For example, system administrators might configure a secondary network interface on cluster nodes after installation for a storage network.

**NOTE**

Configuration must occur before scheduling pods.

State-driven network configuration requires installing **kubernetes-nmstate**, and also requires Network Manager running on the cluster nodes. See [OpenShift Virtualization > Kubernetes NMState \(Tech Preview\)](#) for additional details.

10.2.4. Configuring nodes**Configuring nodes when using the provisioning network**

Each node in the cluster requires the following configuration for proper installation.

**WARNING**

A mismatch between nodes will cause an installation failure.

While the cluster nodes can contain more than two NICs, the installation process only focuses on the first two NICs:

NIC	Network	VLAN
NIC1	provisioning	<provisioning_vlan>
NIC2	baremetal	<baremetal_vlan>

In the foregoing example, NIC1 is a non-routable network (**provisioning**) that is only used for the installation of the OpenShift Container Platform cluster.

The Red Hat Enterprise Linux (RHEL) 8.x installation process on the provisioner node might vary. To install Red Hat Enterprise Linux (RHEL) 8.x using a local Satellite server or a PXE server, PXE-enable NIC2.

PXE	Boot order
NIC1 PXE-enabled provisioning network	1
NIC2 baremetal network. PXE-enabled is optional.	2

**NOTE**

Ensure PXE is disabled on all other NICs.

Configure the control plane and worker nodes as follows:

PXE	Boot order
NIC1 PXE-enabled (provisioning network)	1

Configuring nodes without the provisioning network

The installation process requires one NIC:

NIC	Network	VLAN
NICx	baremetal	<baremetal_vlan>

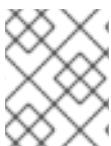

NICx is a routable network (**baremetal**) that is used for the installation of the OpenShift Container Platform cluster, and routable to the internet.

**IMPORTANT**

The **provisioning** network is optional, but it is required for PXE booting. If you deploy without a **provisioning** network, you must use a virtual media BMC addressing option such as **redfish-virtualmedia** or **idrac-virtualmedia**.

Configuring nodes for Secure Boot manually

Secure Boot prevents a node from booting unless it verifies the node is using only trusted software, such as UEFI firmware drivers, EFI applications, and the operating system.

**NOTE**

Red Hat only supports manually configured Secure Boot when deploying with Redfish virtual media.

To enable Secure Boot manually, refer to the hardware guide for the node and execute the following:

1. Boot the node and enter the BIOS menu.
2. Set the node's boot mode to UEFI Enabled.
3. Enable Secure Boot.

**IMPORTANT**

Red Hat does not support Secure Boot with self-generated keys.

10.2.5. Out-of-band management

Nodes will typically have an additional NIC used by the Baseboard Management Controllers (BMCs). These BMCs must be accessible from the **provisioner** node.

Each node must be accessible via out-of-band management. When using an out-of-band management network, the **provisioner** node requires access to the out-of-band management network for a successful OpenShift Container Platform 4 installation.

The out-of-band management setup is out of scope for this document. We recommend setting up a separate management network for out-of-band management. However, using the **provisioning** network or the **baremetal** network are valid options.

10.2.6. Required data for installation

Prior to the installation of the OpenShift Container Platform cluster, gather the following information from all cluster nodes:

- Out-of-band management IP
 - Examples
 - Dell (iDRAC) IP
 - HP (iLO) IP
 - Fujitsu (iRMC) IP

When using the **provisioning** network

- NIC1 (**provisioning**) MAC address
- NIC2 (**baremetal**) MAC address

When omitting the **provisioning** network

- NICx (**baremetal**) MAC address

10.2.7. Validation checklist for nodes

When using the **provisioning** network

- NIC1 VLAN is configured for the **provisioning** network. (optional)
- NIC1 is PXE-enabled on the provisioner, control plane (master), and worker nodes when using a **provisioning** network. (optional)
- NIC2 VLAN is configured for the **baremetal** network.
- PXE has been disabled on all other NICs.
- Control plane and worker nodes are configured.
- All nodes accessible via out-of-band management.
- A separate management network has been created. (optional)
- Required data for installation.

When omitting the provisioning network

- NICx VLAN is configured for the **baremetal** network.
- Control plane and worker nodes are configured.
- All nodes accessible via out-of-band management.
- A separate management network has been created. (optional)
- Required data for installation.

10.3. SETTING UP THE ENVIRONMENT FOR AN OPENSHIFT INSTALLATION

10.3.1. Installing RHEL on the provisioner node

With the networking configuration complete, the next step is to install RHEL 8.x on the provisioner node. The installer uses the provisioner node as the orchestrator while installing the OpenShift Container Platform cluster. For the purposes of this document, installing RHEL on the provisioner node is out of scope. However, options include but are not limited to using a RHEL Satellite server, PXE, or installation media.

10.3.2. Preparing the provisioner node for OpenShift Container Platform installation

Perform the following steps to prepare the environment.

Procedure

1. Log in to the provisioner node via **ssh**.
2. Create a non-root user (**kni**) and provide that user with **sudo** privileges:

```
# useradd kni  
# passwd kni  
# echo "kni ALL=(root) NOPASSWD:ALL" | tee -a /etc/sudoers.d/kni  
# chmod 0440 /etc/sudoers.d/kni
```

3. Create an **ssh** key for the new user:

```
# su - kni -c "ssh-keygen -t ed25519 -f /home/kni/.ssh/id_rsa -N ""
```

4. Log in as the new user on the provisioner node:

```
# su - kni  
$
```

5. Use Red Hat Subscription Manager to register the provisioner node:

```
$ sudo subscription-manager register --username=<user> --password=<pass> --auto-attach  
$ sudo subscription-manager repos --enable=rhel-8-for-x86_64-appstream-rpms --  
enable=rhel-8-for-x86_64-baseos-rpms
```

**NOTE**

For more information about Red Hat Subscription Manager, see [Using and Configuring Red Hat Subscription Manager](#).

6. Install the following packages:

```
$ sudo dnf install -y libvirt qemu-kvm mkisofs python3-devel jq ipmitool
```

7. Modify the user to add the **libvirt** group to the newly created user:

```
$ sudo usermod --append --groups libvirt <user>
```

8. Restart **firewalld** and enable the **http** service:

```
$ sudo systemctl start firewalld
$ sudo firewall-cmd --zone=public --add-service=http --permanent
$ sudo firewall-cmd --reload
```

9. Start and enable the **libvirtd** service:

```
$ sudo systemctl enable libvirtd --now
```

10. Create the **default** storage pool and start it:

```
$ sudo virsh pool-define-as --name default --type dir --target /var/lib/libvirt/images
$ sudo virsh pool-start default
$ sudo virsh pool-autostart default
```

11. Configure networking.

**NOTE**

You can also configure networking from the web console.

Export the **baremetal** network NIC name:

```
$ export PUB_CONN=<baremetal_nic_name>
```

Configure the **baremetal** network:

```
$ sudo nohup bash -c "
nmcli con down \"\$PUB_CONN\"
nmcli con delete \"\$PUB_CONN\"
# RHEL 8.1 appends the word \"System\" in front of the connection, delete in case it exists
nmcli con down \"System \$PUB_CONN\"
nmcli con delete \"System \$PUB_CONN\"
nmcli connection add ifname baremetal type bridge con-name baremetal
nmcli con add type bridge-slave ifname \"\$PUB_CONN\" master baremetal
pkill dhclient;dhclient baremetal
"
```

If you are deploying with a **provisioning** network, export the **provisioning** network NIC name:

```
$ export PROV_CONN=<prov_nic_name>
```

If you are deploying with a **provisioning** network, configure the **provisioning** network:

```
$ sudo nohup bash -c "
    nmcli con down \"$PROV_CONN\"
    nmcli con delete \"$PROV_CONN\"
    nmcli connection add ifname provisioning type bridge con-name provisioning
    nmcli con add type bridge-slave ifname \"$PROV_CONN\" master provisioning
    nmcli connection modify provisioning ipv6.addresses fd00:1101::1/64 ipv6.method manual
    nmcli con down provisioning
    nmcli con up provisioning
"
```

NOTE

The **ssh** connection might disconnect after executing these steps.

The IPv6 address can be any address as long as it is not routable via the **baremetal** network.

Ensure that UEFI is enabled and UEFI PXE settings are set to the IPv6 protocol when using IPv6 addressing.

12. **ssh** back into the **provisioner** node (if required).

```
# ssh kni@provisioner.<cluster-name>.<domain>
```

13. Verify the connection bridges have been properly created.

```
$ sudo nmcli con show
```

NAME	UUID	TYPE	DEVICE
baremetal	4d5133a5-8351-4bb9-bfd4-3af264801530	bridge	baremetal
provisioning	43942805-017f-4d7d-a2c2-7cb3324482ed	bridge	provisioning
virbr0	d9bca40f-eee1-410b-8879-a2d4bb0465e7	bridge	virbr0
bridge-slave-eno1	76a8ed50-c7e5-4999-b4f6-6d9014dd0812	ethernet	eno1
bridge-slave-eno2	f31c3353-54b7-48de-893a-02d2b34c4736	ethernet	eno2

14. Create a **pull-secret.txt** file.

```
$ vim pull-secret.txt
```

In a web browser, navigate to [Install on Bare Metal with user-provisioned infrastructure](#), and scroll down to the **Downloads** section. Click **Copy pull secret**. Paste the contents into the **pull-secret.txt** file and save the contents in the **kni** user's home directory.

10.3.3. Retrieving the OpenShift Container Platform installer

Use the **latest-4.x** version of the installer to deploy the latest generally available version of OpenShift Container Platform:

```
$ export VERSION=latest-4.9
export RELEASE_IMAGE=$(curl -s https://mirror.openshift.com/pub/openshift-v4/clients/ocp/$VERSION/release.txt | grep 'Pull From: quay.io' | awk -F ' ' '{print $3}')
```

10.3.4. Extracting the OpenShift Container Platform installer

After retrieving the installer, the next step is to extract it.

Procedure

1. Set the environment variables:

```
$ export cmd=openshift-baremetal-install
$ export pullsecret_file=~/pull-secret.txt
$ export extract_dir=$(pwd)
```

2. Get the **oc** binary:

```
$ curl -s https://mirror.openshift.com/pub/openshift-v4/clients/ocp/$VERSION/openshift-client-linux.tar.gz | tar zxvf - oc
```

3. Extract the installer:

```
$ sudo cp oc /usr/local/bin
$ oc adm release extract --registry-config "${pullsecret_file}" --command=$cmd --to
"${extract_dir}" ${RELEASE_IMAGE}
$ sudo cp openshift-baremetal-install /usr/local/bin
```

10.3.5. Creating an RHCOS images cache (optional)

To employ image caching, you must download two images: the Red Hat Enterprise Linux CoreOS (RHCOS) image used by the bootstrap VM and the RHCOS image used by the installer to provision the different nodes. Image caching is optional, but especially useful when running the installer on a network with limited bandwidth.

If you are running the installer on a network with limited bandwidth and the RHCOS images download takes more than 15 to 20 minutes, the installer will timeout. Caching images on a web server will help in such scenarios.

Install a container that contains the images.

Procedure

1. Install **podman**:

```
$ sudo dnf install -y podman
```

2. Open firewall port **8080** to be used for RHCOS image caching:

```
$ sudo firewall-cmd --add-port=8080/tcp --zone=public --permanent
```

```
$ sudo firewall-cmd --reload
```

3. Create a directory to store the **bootstrapimage** and **clusterosimage**:

```
$ mkdir /home/kni/rhcos_image_cache
```

4. Set the appropriate SELinux context for the newly created directory:

```
$ sudo semanage fcontext -a -t httpd_sys_content_t "/home/kni/rhcos_image_cache(/.*)?"
```

```
$ sudo restorecon -Rv rhcos_image_cache/
```

5. Get the commit ID from the installer:

```
$ export COMMIT_ID=$(/usr/local/bin/openshift-baremetal-install version | grep '^built from commit' | awk '{print $4}')
```

The ID determines which images the installer needs to download.

6. Get the URI for the RHCOS image that the installer will deploy on the nodes:

```
$ export RHCOSENSTACK_URI=$(curl -s -S https://raw.githubusercontent.com/openshift/installer/$COMMIT_ID/data/data/rhcos.json | jq .images.openstack.path | sed 's://"g')
```

7. Get the URI for the RHCOS image that the installer will deploy on the bootstrap VM:

```
$ export RHCOSE_QEMU_URI=$(curl -s -S https://raw.githubusercontent.com/openshift/installer/$COMMIT_ID/data/data/rhcos.json | jq .images.qemu.path | sed 's://"g')
```

8. Get the path where the images are published:

```
$ export RHCOSENPATH=$(curl -s -S https://raw.githubusercontent.com/openshift/installer/$COMMIT_ID/data/data/rhcos.json | jq .baseURI | sed 's://"g')
```

9. Get the SHA hash for the RHCOS image that will be deployed on the bootstrap VM:

```
$ export RHCOSE_QEMU_SHA_UNCOMPRESSED=$(curl -s -S https://raw.githubusercontent.com/openshift/installer/$COMMIT_ID/data/data/rhcos.json | jq -r '.images.qemu["uncompressed-sha256"]')
```

10. Get the SHA hash for the RHCOS image that will be deployed on the nodes:

```
$ export RHCOSENSTACK_SHA_COMPRESSED=$(curl -s -S https://raw.githubusercontent.com/openshift/installer/$COMMIT_ID/data/data/rhcos.json | jq -r '.images.openstack.sha256')
```

11. Download the images and place them in the **/home/kni/rhcos_image_cache** directory:

```
$ curl -L ${RHCOS_PATH}${RHCOS_QEMU_URI} -o
/home/kni/rhcos_image_cache/${RHCOS_QEMU_URI}
```

```
$ curl -L ${RHCOS_PATH}${RHCOS_OPENSTACK_URI} -o
/home/kni/rhcos_image_cache/${RHCOS_OPENSTACK_URI}
```

12. Confirm SELinux type is of **httpd_sys_content_t** for the newly created files:

```
$ ls -Z /home/kni/rhcos_image_cache
```

13. Create the pod:

```
$ podman run -d --name rhcos_image_cache \
-v /home/kni/rhcos_image_cache:/var/www/html \
-p 8080:8080/tcp \
registry.centos.org/centos/httpd-24-centos7:latest
```

The above command creates a caching webserver with the name **rhcos_image_cache**, which serves the images for deployment. The first image **\${RHCOS_PATH}\${RHCOS_QEMU_URI}?sha256=\${RHCOS_QEMU_SHA_UNCOMPRESSED}** is the **bootstrapOSImage** and the second image **\${RHCOS_PATH}\${RHCOS_OPENSTACK_URI}?sha256=\${RHCOS_OPENSTACK_SHA_COMPRESSED}** is the **clusterOSImage** in the **install-config.yaml** file.

14. Generate the **bootstrapOSImage** and **clusterOSImage** configuration:

```
$ export BAREMETAL_IP=$(ip addr show dev baremetal | awk '/inet /{print $2}' | cut -d"/" -f1)
```

```
$ export RHCOS_OPENSTACK_SHA256=$(zcat
/home/kni/rhcos_image_cache/${RHCOS_OPENSTACK_URI} | sha256sum | awk '{print
$1}')
```

```
$ export RHCOS_QEMU_SHA256=$(zcat
/home/kni/rhcos_image_cache/${RHCOS_QEMU_URI} | sha256sum | awk '{print $1}')
```

```
$ export
CLUSTER_OS_IMAGE="http://${BAREMETAL_IP}:8080/${RHCOS_OPENSTACK_URI}?sha256=${RHCOS_OPENSTACK_SHA256}"
```

```
$ export
BOOTSTRAP_OS_IMAGE="http://${BAREMETAL_IP}:8080/${RHCOS_QEMU_URI}?sha256=${RHCOS_QEMU_SHA256}"
```

```
$ echo "${RHCOS_OPENSTACK_SHA256} ${RHCOS_OPENSTACK_URI}" >
/home/kni/rhcos_image_cache/rhcos-oopfa-latest.qcow2.md5sum
```

```
$ echo " bootstrapOSImage=${BOOTSTRAP_OS_IMAGE}"
```

```
$ echo " clusterOSImage=${CLUSTER_OS_IMAGE}"
```

15. Add the required configuration to the **install-config.yaml** file under **platform.baremetal**:

```
platform:
  baremetal:
    bootstrapOSImage: http://<BAREMETAL_IP>:8080/<RHCOS_QEMU_URI>?sha256=<RHCOS_QEMU_SHA256>
    clusterOSImage: http://<BAREMETAL_IP>:8080/<RHCOS_OPENSTACK_URI>?sha256=<RHCOS_OPENSTACK_SHA256>
```

See the "Configuration files" section for additional details.

10.3.6. Configuration files

10.3.6.1. Configuring the **install-config.yaml** file

The **install-config.yaml** file requires some additional details. Most of the information is teaching the installer and the resulting cluster enough about the available hardware so that it is able to fully manage it.

1. Configure **install-config.yaml**. Change the appropriate variables to match the environment, including **pullSecret** and **sshKey**.

```
apiVersion: v1
baseDomain: <domain>
metadata:
  name: <cluster-name>
networking:
  machineCIDR: <public-cidr>
  networkType: OVNKubernetes
compute:
  - name: worker
    replicas: 2 1
controlPlane:
  name: master
  replicas: 3
  platform:
    baremetal: {}
platform:
  baremetal:
    apiVIP: <api-ip>
    ingressVIP: <wildcard-ip>
    provisioningNetworkCIDR: <CIDR>
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: ipmi://<out-of-band-ip> 2
          username: <user>
          password: <password>
        bootMACAddress: <NIC1-mac-address>
        rootDeviceHints:
          deviceName: "/dev/sda"
      - name: <openshift-master-1>
        role: master
        bmc:
```

```

address: ipmi://<out-of-band-ip> 3
username: <user>
password: <password>
bootMACAddress: <NIC1-mac-address>
rootDeviceHints:
  deviceName: "/dev/sda"
- name: <openshift-master-2>
role: master
bmc:
  address: ipmi://<out-of-band-ip> 4
  username: <user>
  password: <password>
  bootMACAddress: <NIC1-mac-address>
  rootDeviceHints:
    deviceName: "/dev/sda"
- name: <openshift-worker-0>
role: worker
bmc:
  address: ipmi://<out-of-band-ip> 5
  username: <user>
  password: <password>
  bootMACAddress: <NIC1-mac-address>
- name: <openshift-worker-1>
role: worker
bmc:
  address: ipmi://<out-of-band-ip>
  username: <user>
  password: <password>
  bootMACAddress: <NIC1-mac-address>
  rootDeviceHints:
    deviceName: "/dev/sda"
pullSecret: '<pull_secret>'
sshKey: '<ssh_pub_key>'
```

- 1** Scale the worker machines based on the number of worker nodes that are part of the OpenShift Container Platform cluster.

- 2** **3** **4** **5** See the BMC addressing sections for more options.

2. Create a directory to store cluster configs.

```
$ mkdir ~/clusterconfigs
$ cp install-config.yaml ~/clusterconfigs
```

3. Ensure all bare metal nodes are powered off prior to installing the OpenShift Container Platform cluster.

```
$ ipmitool -I lanplus -U <user> -P <password> -H <management-server-ip> power off
```

4. Remove old bootstrap resources if any are left over from a previous deployment attempt.

```
for i in $(sudo virsh list | tail -n +3 | grep bootstrap | awk '{print $2}');
do
  sudo virsh destroy $i;
```

```

    sudo virsh undefine $i;
    sudo virsh vol-delete $i --pool $i;
    sudo virsh vol-delete $i.ign --pool $i;
    sudo virsh pool-destroy $i;
    sudo virsh pool-undefine $i;
done

```

10.3.6.2. Setting proxy settings within the `install-config.yaml` file (optional)

To deploy an OpenShift Container Platform cluster using a proxy, make the following changes to the `install-config.yaml` file.

```

apiVersion: v1
baseDomain: <domain>
proxy:
  httpProxy: http://USERNAME:PASSWORD@proxy.example.com:PORT
  httpsProxy: https://USERNAME:PASSWORD@proxy.example.com:PORT
  noProxy: <WILDCARD_OF_DOMAIN>,<PROVISIONING_NETWORK/CIDR>,
            <BMC_ADDRESS_RANGE/CIDR>

```

The following is an example of `noProxy` with values.

```
noProxy: .example.com,172.22.0.0/24,10.10.0.0/24
```

With a proxy enabled, set the appropriate values of the proxy in the corresponding key/value pair.

Key considerations:

- If the proxy does not have an HTTPS proxy, change the value of `httpsProxy` from `https://` to `http://`.
- If using a provisioning network, include it in the `noProxy` setting, otherwise the installer will fail.
- Set all of the proxy settings as environment variables within the provisioner node. For example, `HTTP_PROXY`, `HTTPS_PROXY`, and `NO_PROXY`.

10.3.6.3. Modifying the `install-config.yaml` file for no provisioning network (optional)

To deploy an OpenShift Container Platform cluster without a **provisioning** network, make the following changes to the `install-config.yaml` file.

```

platform:
baremetal:
  apiVIP: <api_VIP>
  ingressVIP: <ingress_VIP>
  provisioningNetwork: "Disabled" ①

```

- ① Add the `provisioningNetwork` configuration setting, if needed, and set it to **Disabled**.

IMPORTANT

The **provisioning** network is required for PXE booting. If you deploy without a **provisioning** network, you must use a virtual media BMC addressing option such as **redfish-virtualmedia** or **idrac-virtualmedia**. See "Redfish virtual media for HPE iLO" in the "BMC addressing for HPE iLO" section or "Redfish virtual media for Dell iDRAC" in the "BMC addressing for Dell iDRAC" section for additional details.

10.3.6.4. Modifying the `install-config.yaml` file for dual-stack network (optional)

To deploy an OpenShift Container Platform cluster with dual-stack networking, edit the **machineNetwork**, **clusterNetwork**, and **serviceNetwork** configuration settings in the **install-config.yaml** file. Each setting must have two CIDR entries each. Ensure the first CIDR entry is the IPv4 setting and the second CIDR entry is the IPv6 setting.

```
machineNetwork:
- cidr: {{ extcidrnet }}
- cidr: {{ extcidrnet6 }}
clusterNetwork:
- cidr: 10.128.0.0/14
  hostPrefix: 23
- cidr: fd02::/48
  hostPrefix: 64
serviceNetwork:
- 172.30.0.0/16
- fd03::/112
```

IMPORTANT

The API VIP IP address and the Ingress VIP address must be of the primary IP address family when using dual-stack networking. Currently, Red Hat does not support dual-stack VIPs or dual-stack networking with IPv6 as the primary IP address family. However, Red Hat does support dual-stack networking with IPv4 as the primary IP address family. Therefore, the IPv4 entries must go **before** the IPv6 entries.

10.3.6.5. Configuring managed Secure Boot in the `install-config.yaml` file (optional)

You can enable managed Secure Boot when deploying an installer-provisioned cluster using Redfish BMC addressing, such as **redfish**, **redfish-virtualmedia**, or **idrac-virtualmedia**. To enable managed Secure Boot, add the **bootMode** configuration setting to each node:

Example

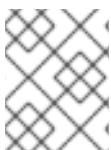

```
hosts:
- name: openshift-master-0
  role: master
  bmc:
    address: redfish://<out_of_band_ip> 1
    username: <user>
    password: <password>
  bootMACAddress: <NIC1_mac_address>
  rootDeviceHints:
    deviceName: "/dev/sda"
  bootMode: UEFISecureBoot 2
```

- 1** Ensure the **bmc.address** setting uses **redfish**, **redfish-virtualmedia**, or **idrac-virtualmedia** as the protocol. See "BMC addressing for HPE iLO" or "BMC addressing for Dell iDRAC" for additional details.
- 2** The **bootMode** setting is **UEFI** by default. Change it to **UEFISecureBoot** to enable managed Secure Boot.

NOTE

See "Configuring nodes" in the "Prerequisites" to ensure the nodes can support managed Secure Boot. If the nodes do not support managed Secure Boot, see "Configuring nodes for Secure Boot manually" in the "Configuring nodes" section. Configuring Secure Boot manually requires Redfish virtual media.

NOTE

Red Hat does not support Secure Boot with IPMI, because IPMI does not provide Secure Boot management facilities.

10.3.6.6. Additional `install-config` parameters

See the following tables for the required parameters, the **hosts** parameter, and the **bmc** parameter for the **install-config.yaml** file.

Table 10.2. Required parameters

Parameters	Default	Description
baseDomain		The domain name for the cluster. For example, example.com .
bootMode	UEFI	The boot mode for a node. Options are legacy , UEFI , and UEFISecureBoot . If bootMode is not set, Ironic sets it while inspecting the node.
sshKey		The sshKey configuration setting contains the key in the ~/.ssh/id_rsa.pub file required to access the control plane nodes and worker nodes. Typically, this key is from the provisioner node.
pullSecret		The pullSecret configuration setting contains a copy of the pull secret downloaded from the Install OpenShift on Bare Metal page when preparing the provisioner node.

Parameters	Default	Description
metadata: name:		The name to be given to the OpenShift Container Platform cluster. For example, openshift .
networking: machineCIDR:		The public CIDR (Classless Inter-Domain Routing) of the external network. For example, 10.0.0.0/24 .
compute: - name: worker		The OpenShift Container Platform cluster requires a name be provided for worker (or compute) nodes even if there are zero nodes.
compute: replicas: 2		Replicas sets the number of worker (or compute) nodes in the OpenShift Container Platform cluster.
controlPlane: name: master		The OpenShift Container Platform cluster requires a name for control plane (master) nodes.
controlPlane: replicas: 3		Replicas sets the number of control plane (master) nodes included as part of the OpenShift Container Platform cluster.
provisioningNetworkInterface		The name of the network interface on nodes connected to the provisioning network. For OpenShift Container Platform 4.9 and later releases, use the bootMACAddress configuration setting to enable Ironic to identify the IP address of the NIC instead of using the provisioningNetworkInterface configuration setting to identify the name of the NIC.
defaultMachinePlatform		The default configuration used for machine pools without a platform configuration.

Parameters	Default	Description
apiVIP	<code>api. <clustername.clusterdomain ></code>	The VIP to use for internal API communication. This setting must either be provided or pre-configured in the DNS so that the default name resolves correctly.
disableCertificateVerification	False	redfish and redfish-virtualmedia need this parameter to manage BMC addresses. The value should be True when using a self-signed certificate for BMC addresses.
ingressVIP	<code>test.apps. <clustername.clusterdomain ></code>	The VIP to use for ingress traffic.

Table 10.3. Optional Parameters

Parameters	Default	Description
provisioningDHCPRange	172.22.0.10,172.22.0.100	Defines the IP range for nodes on the provisioning network.
provisioningNetworkCIDR	172.22.0.0/24	The CIDR for the network to use for provisioning. This option is required when not using the default address range on the provisioning network.
clusterProvisioningIP	The third IP address of the provisioningNetworkCIDR .	The IP address within the cluster where the provisioning services run. Defaults to the third IP address of the provisioning subnet. For example, 172.22.0.3 .
bootstrapProvisioningIP	The second IP address of the provisioningNetworkCIDR .	The IP address on the bootstrap VM where the provisioning services run while the installer is deploying the control plane (master) nodes. Defaults to the second IP address of the provisioning subnet. For example, 172.22.0.2 or 2620:52:0:1307::2 .
externalBridge	baremetal	The name of the baremetal bridge of the hypervisor attached to the baremetal network.
provisioningBridge	provisioning	The name of the provisioning bridge on the provisioner host attached to the provisioning network.

Parameters	Default	Description
defaultMachinePlatform		The default configuration used for machine pools without a platform configuration.
bootstrapOSImage		A URL to override the default operating system image for the bootstrap node. The URL must contain a SHA-256 hash of the image. For example: <a href="https://mirror.openshift.com/rhcos-<version>-qemu.qcow2.gz?sha256=<uncompressed_sha256>">https://mirror.openshift.com/rhcos-<version>-qemu.qcow2.gz?sha256=<uncompressed_sha256> .
clusterOSImage		A URL to override the default operating system for cluster nodes. The URL must include a SHA-256 hash of the image. For example, <a href="https://mirror.openshift.com/images/rhcos-<version>-openstack.qcow2.gz?sha256=<compressed_sha256>">https://mirror.openshift.com/images/rhcos-<version>-openstack.qcow2.gz?sha256=<compressed_sha256> .
provisioningNetwork		<p>The provisioningNetwork configuration setting determines whether the cluster uses the provisioning network. If it does, the configuration setting also determines if the cluster manages the network.</p> <p>Disabled: Set this parameter to Disabled to disable the requirement for a provisioning network. When set to Disabled, you must only use virtual media based provisioning, or bring up the cluster using the assisted installer. If Disabled and using power management, BMCs must be accessible from the baremetal network. If Disabled, you must provide two IP addresses on the baremetal network that are used for the provisioning services.</p> <p>Managed: Set this parameter to Managed, which is the default, to fully manage the provisioning network, including DHCP, TFTP, and so on.</p> <p>Unmanaged: Set this parameter to Unmanaged to enable the provisioning network but take care of manual configuration of DHCP. Virtual media provisioning is recommended but PXE is still available if required.</p>
httpProxy		Set this parameter to the appropriate HTTP proxy used within your environment.
httpsProxy		Set this parameter to the appropriate HTTPS proxy used within your environment.
noProxy		Set this parameter to the appropriate list of exclusions for proxy usage within your environment.

Hosts

The **hosts** parameter is a list of separate bare metal assets used to build the cluster.

Table 10.4. Hosts

Name	Default	Description
name		The name of the BareMetalHost resource to associate with the details. For example, openshift-master-0 .
role		The role of the bare metal node. Either master or worker .
bmc		Connection details for the baseboard management controller. See the BMC addressing section for additional details.
bootMACAddress		The MAC address of the NIC that the host uses for the provisioning network. Ironic retrieves the IP address using the bootMACAddress configuration setting. Then, it binds to the host.

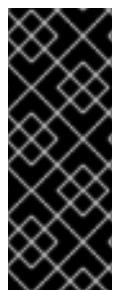

10.3.6.7. BMC addressing

Most vendors support Baseboard Management Controller (BMC) addressing with the Intelligent Platform Management Interface (IPMI). IPMI does not encrypt communications. It is suitable for use within a data center over a secured or dedicated management network. Check with your vendor to see if they support Redfish network boot. Redfish delivers simple and secure management for converged, hybrid IT and the Software Defined Data Center (SDDC). Redfish is human readable and machine capable, and leverages common internet and web services standards to expose information directly to the modern tool chain. If your hardware does not support Redfish network boot, use IPMI.

IPMI

Hosts using IPMI use the **ipmi://<out-of-band-ip>:<port>** address format, which defaults to port **623** if not specified. The following example demonstrates an IPMI configuration within the **install-config.yaml** file.

```
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: ipmi://<out-of-band-ip>
          username: <user>
          password: <password>
```

IMPORTANT

The **provisioning** network is required when PXE booting using IPMI for BMC addressing. It is not possible to PXE boot hosts without a **provisioning** network. If you deploy without a **provisioning** network, you must use a virtual media BMC addressing option such as **redfish-virtualmedia** or **idrac-virtualmedia**. See "Redfish virtual media for HPE iLO" in the "BMC addressing for HPE iLO" section or "Redfish virtual media for Dell iDRAC" in the "BMC addressing for Dell iDRAC" section for additional details.

Redfish network boot

To enable Redfish, use `redfish://` or `redfish+http://` to disable TLS. The installer requires both the hostname or the IP address and the path to the system ID. The following example demonstrates a Redfish configuration within the `install-config.yaml` file.

```
platform:
baremetal:
hosts:
- name: openshift-master-0
role: master
bmc:
address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
username: <user>
password: <password>
```

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include **disableCertificateVerification: True** in the **bmc** configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the **disableCertificateVerification: True** configuration parameter within the `install-config.yaml` file.

```
platform:
baremetal:
hosts:
- name: openshift-master-0
role: master
bmc:
address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
username: <user>
password: <password>
disableCertificateVerification: True
```

10.3.6.8. BMC addressing for Dell iDRAC

The **address** field for each **bmc** entry is a URL for connecting to the OpenShift Container Platform cluster nodes, including the type of controller in the URL scheme and its location on the network.

```
platform:
baremetal:
hosts:
- name: <hostname>
role: <master | worker>
bmc:
address: <address> ①
username: <user>
password: <password>
```

① The **address** configuration setting specifies the protocol.

For Dell hardware, Red Hat supports integrated Dell Remote Access Controller (iDRAC) virtual media, Redfish network boot, and IPMI.

BMC address formats for Dell iDRAC

Protocol	Address Format
iDRAC virtual media	idrac-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
Redfish network boot	redfish://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
IPMI	ipmi://<out-of-band-ip>

IMPORTANT

Use **idrac-virtualmedia** as the protocol for Redfish virtual media. **redfish-virtualmedia** will not work on Dell hardware. Dell's **idrac-virtualmedia** uses the Redfish standard with Dell's OEM extensions.

See the following sections for additional details.

Redfish virtual media for Dell iDRAC

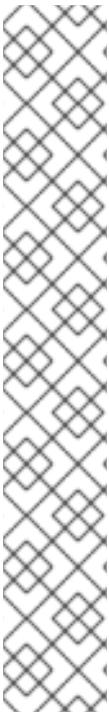

For Redfish virtual media on Dell servers, use **idrac-virtualmedia://** in the **address** setting. Using **redfish-virtualmedia://** will not work.

The following example demonstrates using iDRAC virtual media within the **install-config.yaml** file.

```
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: idrac-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
          username: <user>
          password: <password>
```

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include **disableCertificateVerification: True** in the **bmc** configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the **disableCertificateVerification: True** configuration parameter within the **install-config.yaml** file.

```
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: idrac-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
          username: <user>
          password: <password>
          disableCertificateVerification: True
```

NOTE

Currently, Redfish is only supported on Dell with iDRAC firmware versions **4.20.20.20** through **04.40.00.00** for installer-provisioned installations on bare metal deployments. There is a known issue with version **04.40.00.00**. With iDRAC 9 firmware version **04.40.00.00**, the Virtual Console plug-in defaults to **eHTML5**, which causes problems with the **InsertVirtualMedia** workflow. Set the plug-in to **HTML5** to avoid this issue. The menu path is: **Configuration → Virtual console → Plug-in Type → HTML5**.

Ensure the OpenShift Container Platform cluster nodes have AutoAttach Enabled through the iDRAC console. The menu path is: **Configuration → Virtual Media → Attach Mode → AutoAttach**.

Use **idrac-virtualmedia://** as the protocol for Redfish virtual media. Using **redfish-virtualmedia://** will not work on Dell hardware, because the **idrac-virtualmedia://** protocol corresponds to the **idrac** hardware type and the Redfish protocol in Ironic. Dell's **idrac-virtualmedia://** protocol uses the Redfish standard with Dell's OEM extensions. Ironic also supports the **idrac** type with the WSMAN protocol. Therefore, you must specify **idrac-virtualmedia://** to avoid unexpected behavior when electing to use Redfish with virtual media on Dell hardware.

Redfish network boot for iDRAC

To enable Redfish, use **redfish://** or **redfish+http://** to disable transport layer security (TLS). The installer requires both the hostname or the IP address and the path to the system ID. The following example demonstrates a Redfish configuration within the **install-config.yaml** file.

```
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: redfish://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
          username: <user>
          password: <password>
```

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include **disableCertificateVerification: True** in the **bmc** configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the **disableCertificateVerification: True** configuration parameter within the **install-config.yaml** file.

```
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: redfish://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
          username: <user>
          password: <password>
          disableCertificateVerification: True
```

NOTE

Currently, Redfish is only supported on Dell hardware with iDRAC firmware versions **4.20.20.20** through **04.40.00.00** for installer-provisioned installations on bare metal deployments. There is a known issue with version **04.40.00.00**. With iDRAC 9 firmware version **04.40.00.00**, the Virtual Console plug-in defaults to **eHTML5**, which causes problems with the **InsertVirtualMedia** workflow. Set the plug-in to **HTML5** to avoid this issue. The menu path is: **Configuration → Virtual console → Plug-in Type → HTML5**.

Ensure the OpenShift Container Platform cluster nodes have AutoAttach Enabled through the iDRAC console. The menu path is: **Configuration → Virtual Media → Attach Mode → AutoAttach**.

The **redfish://** URL protocol corresponds to the **redfish** hardware type in ironic.

10.3.6.9. BMC addressing for HPE iLO

The **address** field for each **bmc** entry is a URL for connecting to the OpenShift Container Platform cluster nodes, including the type of controller in the URL scheme and its location on the network.

```
platform:  
baremetal:  
hosts:  
  - name: <hostname>  
    role: <master | worker>  
    bmc:  
      address: <address> ①  
      username: <user>  
      password: <password>
```

- ① The **address** configuration setting specifies the protocol.

For HPE integrated Lights Out (iLO), Red Hat supports Redfish virtual media, Redfish network boot, and IPMI.

Table 10.5. BMC address formats for HPE iLO

Protocol	Address Format
Redfish virtual media	redfish-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/1
Redfish network boot	redfish://<out-of-band-ip>/redfish/v1/Systems/1
IPMI	ipmi://<out-of-band-ip>

See the following sections for additional details.

Redfish virtual media for HPE iLO

To enable Redfish virtual media for HPE servers, use **redfish-virtualmedia://** in the **address** setting. The following example demonstrates using Redfish virtual media within the **install-config.yaml** file.

```
platform:
```

```

baremetal:
  hosts:
    - name: openshift-master-0
      role: master
      bmc:
        address: redfish-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/1
        username: <user>
        password: <password>

```

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include **disableCertificateVerification: True** in the **bmc** configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the **disableCertificateVerification: True** configuration parameter within the **install-config.yaml** file.

```

platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: redfish-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/1
          username: <user>
          password: <password>
          disableCertificateVerification: True

```

NOTE

Redfish virtual media is not supported on 9th generation systems running iLO4, because Ironic does not support iLO4 with virtual media.

Redfish network boot for HPE iLO

To enable Redfish, use **redfish://** or **redfish+http://** to disable TLS. The installer requires both the hostname or the IP address and the path to the system ID. The following example demonstrates a Redfish configuration within the **install-config.yaml** file.

```

platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
          username: <user>
          password: <password>

```

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include **disableCertificateVerification: True** in the **bmc** configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the **disableCertificateVerification: True** configuration parameter within the **install-config.yaml** file.

```

platform:
  baremetal:
    hosts:
      - name: openshift-master-0

```

```

role: master
bmc:
  address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
  username: <user>
  password: <password>
  disableCertificateVerification: True

```

10.3.6.10. BMC addressing for Fujitsu iRMC

The **address** field for each **bmc** entry is a URL for connecting to the OpenShift Container Platform cluster nodes, including the type of controller in the URL scheme and its location on the network.

```

platform:
baremetal:
hosts:
- name: <hostname>
  role: <master | worker>
bmc:
  address: <address> ①
  username: <user>
  password: <password>

```

- ① The **address** configuration setting specifies the protocol.

For Fujitsu hardware, Red Hat supports integrated Remote Management Controller (iRMC) and IPMI.

Table 10.6. BMC address formats for Fujitsu iRMC

Protocol	Address Format
iRMC	irmc://<out-of-band-ip>
IPMI	ipmi://<out-of-band-ip>

iRMC

Fujitsu nodes can use **irmc://<out-of-band-ip>** and defaults to port **623**. The following example demonstrates an iRMC configuration within the **install-config.yaml** file.

```

platform:
baremetal:
hosts:
- name: openshift-master-0
  role: master
bmc:
  address: irmc://<out-of-band-ip>
  username: <user>
  password: <password>

```

**NOTE**

Currently Fujitsu supports iRMC S5 firmware version 3.05P and above for installer-provisioned installation on bare metal.

10.3.6.11. Root device hints

The **rootDeviceHints** parameter enables the installer to provision the Red Hat Enterprise Linux CoreOS (RHCOS) image to a particular device. The installer examines the devices in the order it discovers them, and compares the discovered values with the hint values. The installer uses the first discovered device that matches the hint value. The configuration can combine multiple hints, but a device must match all hints for the installer to select it.

Table 10.7. Subfields

Subfield	Description
deviceName	A string containing a Linux device name like /dev/vda . The hint must match the actual value exactly.
hctl	A string containing a SCSI bus address like 0:0:0:0 . The hint must match the actual value exactly.
model	A string containing a vendor-specific device identifier. The hint can be a substring of the actual value.
vendor	A string containing the name of the vendor or manufacturer of the device. The hint can be a substring of the actual value.
serialNumber	A string containing the device serial number. The hint must match the actual value exactly.
minSizeGigabytes	An integer representing the minimum size of the device in gigabytes.
wwn	A string containing the unique storage identifier. The hint must match the actual value exactly.
wwnWithExtension	A string containing the unique storage identifier with the vendor extension appended. The hint must match the actual value exactly.
wwnVendorExtension	A string containing the unique vendor storage identifier. The hint must match the actual value exactly.
rotational	A boolean indicating whether the device should be a rotating disk (true) or not (false).

Example usage

```
- name: master-0
  role: master
  bmc:
    address: ipmi://10.10.0.3:6203
    username: admin
    password: redhat
  bootMACAddress: de:ad:be:ef:00:40
  rootDeviceHints:
    deviceName: "/dev/sda"
```

10.3.6.12. Creating the OpenShift Container Platform manifests

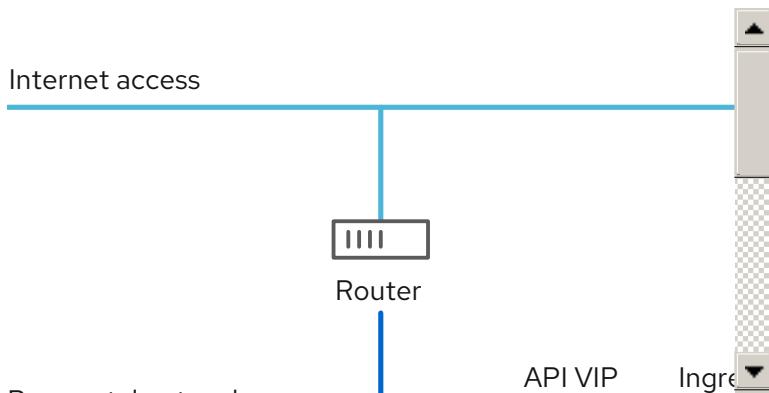

1. Create the OpenShift Container Platform manifests.

```
$ ./openshift-baremetal-install --dir ~/clusterconfigs create manifests
```

INFO Consuming Install Config from target directory
 WARNING Making control-plane schedulable by setting MastersSchedulable to true for Scheduler cluster settings
 WARNING Discarding the OpenShift Manifest that was provided in the target directory because its dependencies are dirty and it needs to be regenerated

10.3.6.13. Configuring NTP for disconnected clusters (optional)

OpenShift Container Platform installs the **chrony** Network Time Protocol (NTP) service on the cluster nodes. Use the following procedure to configure NTP servers on the control plane nodes and configure worker nodes as NTP clients of the control plane nodes before deployment.

OpenShift Container Platform nodes must agree on a date and time to run properly. When worker nodes retrieve the date and time from the NTP servers on the control plane nodes, it enables the installation and operation of clusters that are not connected to a routable network and thereby do not have access to a higher stratum NTP server.

Procedure

1. Create a Butane config, **99-master-chrony-conf-override.bu**, including the contents of the **chrony.conf** file for the control plane nodes.

**NOTE**

See "Creating machine configs with Butane" for information about Butane.

Butane config example

```

variant: openshift
version: 4.9.0
metadata:
  name: 99-master-chrony-conf-override
  labels:
    machineconfiguration.openshift.io/role: master
storage:
  files:
    - path: /etc/chrony.conf
      mode: 0644
      overwrite: true
      contents:
        inline: |
          # Use public servers from the pool.ntp.org project.
          # Please consider joining the pool (https://www.pool.ntp.org/join.html).

          # The Machine Config Operator manages this file
          server openshift-master-0.<cluster-name>.<domain> iburst ①
          server openshift-master-1.<cluster-name>.<domain> iburst
          server openshift-master-2.<cluster-name>.<domain> iburst

          stratumweight 0
          driftfile /var/lib/chrony/drift
          rtcsync
          makestep 10 3
          bindcmdaddress 127.0.0.1
          bindcmdaddress ::1
          keyfile /etc/chrony.keys
          commandkey 1
          generatecommandkey
          noclientlog
          logchange 0.5
          logdir /var/log/chrony

          # Configure the control plane nodes to serve as local NTP servers
          # for all worker nodes, even if they are not in sync with an
          # upstream NTP server.

          # Allow NTP client access from the local network.
          allow all
          # Serve time even if not synchronized to a time source.
          local stratum 3 orphan

```

- 1 You must replace **<cluster-name>** with the name of the cluster and replace **<domain>** with the fully qualified domain name.

2. Use Butane to generate a **MachineConfig** object file, **99-master-chrony-conf-override.yaml**, containing the configuration to be delivered to the control plane nodes:

```
$ butane 99-master-chrony-conf-override.bu -o 99-worker-chrony-conf-override.yaml
```

3. Create a Butane config, **99-worker-chrony-conf-override.bu**, including the contents of the **chrony.conf** file for the worker nodes that references the NTP servers on the control plane nodes.

Butane config example

```
variant: openshift
version: 4.9.0
metadata:
  name: 99-worker-chrony-conf-override
  labels:
    machineconfiguration.openshift.io/role: worker
storage:
  files:
    - path: /etc/chrony.conf
      mode: 0644
      overwrite: true
      contents:
        inline: |
          # The Machine Config Operator manages this file.
          server openshift-master-0.<cluster-name>.<domain> iburst ①
          server openshift-master-1.<cluster-name>.<domain> iburst
          server openshift-master-2.<cluster-name>.<domain> iburst

          stratumweight 0
          driftfile /var/lib/chrony/drift
          rtcsync
          makestep 10 3
          bindcmdaddress 127.0.0.1
          bindcmdaddress ::1
          keyfile /etc/chrony.keys
          commandkey 1
          generatecommandkey
          noclientlog
          logchange 0.5
          logdir /var/log/chrony
```

- ① You must replace **<cluster-name>** with the name of the cluster and replace **<domain>** with the fully qualified domain name.

4. Use Butane to generate a **MachineConfig** object file, **99-worker-chrony-conf-override.yaml**, containing the configuration to be delivered to the worker nodes:

```
$ butane 99-worker-chrony-conf-override.bu -o 99-worker-chrony-conf-override.yaml
```

5. Copy the **99-worker-chrony-conf-override.yaml** file to the **~/clusterconfigs/manifests** directory.

```
$ cp 99-worker-chrony-conf-override.yaml ~/clusterconfigs/manifests
```

- b. Copy the **99-worker-chrony-conf-override.yaml** file to the `~/clusterconfigs/manifests` directory.

```
$ cp 99-worker-chrony-conf-override.yaml ~/clusterconfigs/manifests
```

10.3.6.14. Configure network components to run on the control plane

Configure networking components to run exclusively on the control plane nodes. By default, OpenShift Container Platform allows any node in the machine config pool to host the **apiVIP** and **ingressVIP** virtual IP addresses. However, many environments deploy worker nodes in separate subnets from the control plane nodes. Consequently, you must place the **apiVIP** and **ingressVIP** virtual IP addresses exclusively with the control plane nodes.

Procedure

1. Change to the directory storing the **install-config.yaml** file:

```
$ cd ~/clusterconfigs
```

2. Switch to the **manifests** subdirectory:

```
$ cd manifests
```

3. Create a file named **cluster-network-avoid-workers-99-config.yaml**:

```
$ touch cluster-network-avoid-workers-99-config.yaml
```

4. Open the **cluster-network-avoid-workers-99-config.yaml** file in an editor and enter a custom resource (CR) that describes the Operator configuration:

```
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  name: 50-worker-fix-ipi-rwn
  labels:
    machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    systemd:
      units:
        - name: nodeip-configuration.service
          enabled: true
          contents: |
            [Unit]
            Description=Writes IP address configuration so that kubelet and crio services select a valid node IP
            Wants=network-online.target
            After=network-online.target ignition-firstboot-complete.service
            Before=kubelet.service crio.service
            [Service]
            Type=oneshot
            ExecStart=/bin/bash -c "exit 0 "
```

```
[Install]
WantedBy=multi-user.target

storage:
  files:
    - path: /etc/kubernetes/manifests/keepalived.yaml
      mode: 0644
      contents:
        source: data:,
    - path: /etc/kubernetes/manifests/mdns-publisher.yaml
      mode: 0644
      contents:
        source: data:,
    - path: /etc/kubernetes/manifests/coredns.yaml
      mode: 0644
      contents:
        source: data:,
```

This manifest places the **apiVIP** and **ingressVIP** virtual IP addresses on the control plane nodes. Additionally, this manifest deploys the following processes on the control plane nodes only:

- **openshift-ingress-operator**
- **keepalived**

5. Save the **cluster-network-avoid-workers-99-config.yaml** file.
6. Create a **manifests/cluster-ingress-default-ingresscontroller.yaml** file:

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  nodePlacement:
    nodeSelector:
      matchLabels:
        node-role.kubernetes.io/master: ""
```

7. Consider backing up the **manifests** directory. The installer deletes the **manifests/** directory when creating the cluster.
8. Modify the **cluster-scheduler-02-config.yml** manifest to make the control plane nodes schedulable by setting the **mastersSchedulable** field to **true**. Control plane nodes are not schedulable by default. For example:

```
$ sed -i "s;mastersSchedulable: false;mastersSchedulable: true;g"
clusterconfigs/manifests/cluster-scheduler-02-config.yml
```

NOTE

If control plane nodes are not schedulable, deploying the cluster will fail.

9. Before deploying the cluster, ensure that the **api.<cluster-name>.<domain>** domain name is resolvable in the external DNS server. When you configure network components to run

exclusively on the control plane, the internal DNS resolution no longer works for worker nodes, which is an expected outcome.

IMPORTANT

Failure to create a DNS record for the `api.<cluster-name>.<domain>` domain name in the external DNS server precludes worker nodes from joining the cluster.

10.3.6.15. Configuring BIOS for worker node

The following procedure configures BIOS for the worker node during the installation process.

Procedure

1. Create manifests.
2. Modify the BMH file corresponding to the worker:

```
$ vim clusterconfigs/openshift/99_openshift-cluster-api_hosts-3.yaml
```

3. Add the BIOS configuration to the **spec** section of the BMH file:

```
spec:
  firmware:
    simultaneousMultithreadingEnabled: true
    sriovEnabled: true
    virtualizationEnabled: true
```

NOTE

1. Red Hat supports three BIOS configurations. See the [BMH documentation](#) for details. Only servers with bmc type **irmc** are supported. Other types of servers are currently not supported.

4. Create cluster.

10.3.7. Creating a disconnected registry (optional)

In some cases, you might want to install an OpenShift Container Platform cluster using a local copy of the installation registry. This could be for enhancing network efficiency because the cluster nodes are on a network that does not have access to the internet.

A local, or mirrored, copy of the registry requires the following:

- A certificate for the registry node. This can be a self-signed certificate.
- A web server that a container on a system will serve.
- An updated pull secret that contains the certificate and local repository information.

**NOTE**

Creating a disconnected registry on a registry node is optional. The subsequent sections indicate that they are optional since they are steps you need to execute only when creating a disconnected registry on a registry node. You should execute all of the subsequent sub-sections labeled "(optional)" when creating a disconnected registry on a registry node.

10.3.7.1. Preparing the registry node to host the mirrored registry (optional)

Make the following changes to the registry node.

Procedure

1. Open the firewall port on the registry node.

```
$ sudo firewall-cmd --add-port=5000/tcp --zone=libvirt --permanent
$ sudo firewall-cmd --add-port=5000/tcp --zone=public --permanent
$ sudo firewall-cmd --reload
```

2. Install the required packages for the registry node.

```
$ sudo yum -y install python3 podman httpd httpd-tools jq
```

3. Create the directory structure where the repository information will be held.

```
$ sudo mkdir -p /opt/registry/{auth,certs,data}
```

10.3.7.2. Generating the self-signed certificate (optional)

Generate a self-signed certificate for the registry node and put it in the **/opt/registry/certs** directory.

Procedure

1. Adjust the certificate information as appropriate.

```
$ host_fqdn=$( hostname --long )
$ cert_c=<Country Name> # Country Name (C, 2 letter code)
$ cert_s=<State> # Certificate State (S)
$ cert_l=<Locality> # Certificate Locality (L)
$ cert_o=<Organization> # Certificate Organization (O)
$ cert_ou=<Org Unit> # Certificate Organizational Unit (OU)
$ cert_cn="${host_fqdn}" # Certificate Common Name (CN)

$ openssl req \
    -newkey rsa:4096 \
    -nodes \
    -sha256 \
    -keyout /opt/registry/certs/domain.key \
    -x509 \
    -days 365 \
    -out /opt/registry/certs/domain.crt \
    -addext "subjectAltName = DNS:${host_fqdn}" \
    -subj "/C=${cert_c}/ST=${cert_s}/L=${cert_l}/O=${cert_o}/OU=${cert_ou}/CN=${cert_cn}"
```

**NOTE**

When replacing **<Country Name>**, ensure that it only contains two letters. For example, **US**.

2. Update the registry node's **ca-trust** with the new certificate.

```
$ sudo cp /opt/registry/certs/domain.crt /etc/pki/ca-trust/source/anchors/
$ sudo update-ca-trust extract
```

10.3.7.3. Creating the registry podman container (optional)

The registry container uses the **/opt/registry** directory for certificates, authentication files, and to store its data files.

The registry container uses **httpd** and needs an **htpasswd** file for authentication.

Procedure

1. Create an **htpasswd** file in **/opt/registry/auth** for the container to use.

```
$ htpasswd -bBc /opt/registry/auth/htpasswd <user> <passwd>
```

Replace **<user>** with the user name and **<passwd>** with the password.

2. Create and start the registry container.

```
$ podman create \
--name ocpdiscon-registry \
-p 5000:5000 \
-e "REGISTRY_AUTH=htpasswd" \
-e "REGISTRY_AUTH_HTPASSWD_REALM=Registry" \
-e "REGISTRY_HTTP_SECRET=ALongRandomSecretForRegistry" \
-e "REGISTRY_AUTH_HTPASSWD_PATH=/auth/htpasswd" \
-e "REGISTRY_HTTP_TLS_CERTIFICATE=/certs/domain.crt" \
-e "REGISTRY_HTTP_TLS_KEY=/certs/domain.key" \
-e "REGISTRY_COMPATIBILITY_SCHEMA1_ENABLED=true" \
-v /opt/registry/data:/var/lib/registry:z \
-v /opt/registry/auth:/auth:z \
-v /opt/registry/certs:/certs:z \
docker.io/library/registry:2
```

```
$ podman start ocpdiscon-registry
```

10.3.7.4. Copy and update the pull-secret (optional)

Copy the pull secret file from the provisioner node to the registry node and modify it to include the authentication information for the new registry node.

Procedure

1. Copy the **pull-secret.txt** file.

```
$ scp kni@provisioner:/home/kni/pull-secret.txt pull-secret.txt
```

2. Update the **host_fqdn** environment variable with the fully qualified domain name of the registry node.

```
$ host_fqdn=$( hostname --long )
```

3. Update the **b64auth** environment variable with the base64 encoding of the **http** credentials used to create the **htpasswd** file.

```
$ b64auth=$( echo -n '<username>:<passwd>' | openssl base64 )
```

Replace **<username>** with the user name and **<passwd>** with the password.

4. Set the **AUTHSTRING** environment variable to use the **base64** authorization string. The **\$USER** variable is an environment variable containing the name of the current user.

```
$ AUTHSTRING={"\"$host_fqdn:5000\": {\"auth\": \"$b64auth\", \"email\": \"$USER@redhat.com\"}}"
```

5. Update the **pull-secret.txt** file.

```
$ jq ".auths += $AUTHSTRING" < pull-secret.txt > pull-secret-update.txt
```

10.3.7.5. Mirroring the repository (optional)

Procedure

1. Copy the **oc** binary from the provisioner node to the registry node.

```
$ sudo scp kni@provisioner:/usr/local/bin/oc /usr/local/bin
```

2. Mirror the remote install images to the local repository.

```
$ /usr/local/bin/oc adm release mirror \
-a pull-secret-update.txt
--from=$UPSTREAM_REPO \
--to-release-image=$LOCAL_REG/$LOCAL_REPO:${VERSION} \
--to=$LOCAL_REG/$LOCAL_REPO
```

10.3.7.6. Modify the **install-config.yaml** file to use the disconnected registry (optional)

On the provisioner node, the **install-config.yaml** file should use the newly created pull-secret from the **pull-secret-update.txt** file. The **install-config.yaml** file must also contain the disconnected registry node's certificate and registry information.

Procedure

1. Add the disconnected registry node's certificate to the **install-config.yaml** file. The certificate should follow the **"additionalTrustBundle: |"** line and be properly indented, usually by two spaces.

```
$ echo "additionalTrustBundle: |" >> install-config.yaml
$ sed -e 's/^/ /' /opt/registry/certs/domain.crt >> install-config.yaml
```

2. Add the mirror information for the registry to the **install-config.yaml** file.

```
$ echo "imageContentSources:" >> install-config.yaml
$ echo "- mirrors:" >> install-config.yaml
$ echo " - registry.example.com:5000/ocp4/openshift4" >> install-config.yaml
$ echo " source: quay.io/openshift-release-dev/ocp-release" >> install-config.yaml
$ echo "- mirrors:" >> install-config.yaml
$ echo " - registry.example.com:5000/ocp4/openshift4" >> install-config.yaml
$ echo " source: quay.io/openshift-release-dev/ocp-v4.0-art-dev" >> install-config.yaml
```

NOTE

Replace **registry.example.com** with the registry's fully qualified domain name.

10.3.8. Deploying routers on worker nodes

During installation, the installer deploys router pods on worker nodes. By default, the installer installs two router pods. If the initial cluster has only one worker node, or if a deployed cluster requires additional routers to handle external traffic loads destined for services within the OpenShift Container Platform cluster, you can create a **yaml** file to set an appropriate number of router replicas.

NOTE

By default, the installer deploys two routers. If the cluster has at least two worker nodes, you can skip this section.

NOTE

If the cluster has no worker nodes, the installer deploys the two routers on the control plane nodes by default. If the cluster has no worker nodes, you can skip this section.

Procedure

1. Create a **router-replicas.yaml** file.

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  replicas: <num-of-router-pods>
  endpointPublishingStrategy:
    type: HostNetwork
  nodePlacement:
    nodeSelector:
      matchLabels:
        node-role.kubernetes.io/worker: ""
```

**NOTE**

Replace **<num-of-router-pods>** with an appropriate value. If working with just one worker node, set **replicas:** to **1**. If working with more than 3 worker nodes, you can increase **replicas:** from the default value **2** as appropriate.

- Save and copy the **router-replicas.yaml** file to the **clusterconfigs/openshift** directory.

```
cp ~/router-replicas.yaml clusterconfigs/openshift/99_router-replicas.yaml
```

10.3.9. Validation checklist for installation

- OpenShift Container Platform installer has been retrieved.
- OpenShift Container Platform installer has been extracted.
- Required parameters for the **install-config.yaml** have been configured.
- The **hosts** parameter for the **install-config.yaml** has been configured.
- The **bmc** parameter for the **install-config.yaml** has been configured.
- Conventions for the values configured in the **bmc address** field have been applied.
- Created a disconnected registry (optional).
- (optional) Validate disconnected registry settings if in use.
- (optional) Deployed routers on worker nodes.

10.3.10. Deploying the cluster via the OpenShift Container Platform installer

Run the OpenShift Container Platform installer:

```
$ ./openshift-baremetal-install --dir ~/clusterconfigs --log-level debug create cluster
```

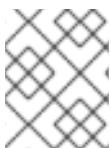

10.3.11. Following the installation

During the deployment process, you can check the installation's overall status by issuing the **tail** command to the **.openshift_install.log** log file in the install directory folder.

```
$ tail -f /path/to/install-dir/.openshift_install.log
```

10.3.12. Verifying static IP address configuration

If the DHCP reservation for a cluster node specifies an infinite lease, after the installer successfully provisions the node, the dispatcher script checks the node's network configuration. If the script determines that the network configuration contains an infinite DHCP lease, it creates a new connection using the IP address of the DHCP lease as a static IP address.

**NOTE**

The dispatcher script might run on successfully provisioned nodes while the provisioning of other nodes in the cluster is ongoing.

Verify the network configuration is working properly.

Procedure

1. Check the network interface configuration on the node.
2. Turn off the DHCP server and reboot the OpenShift Container Platform node and ensure that the network configuration works properly.

Additional resources

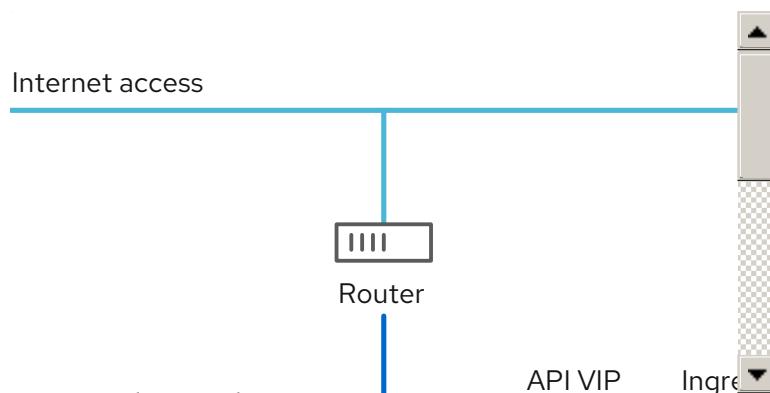

- See [OpenShift Container Platform upgrade channels and releases](#) for an explanation of the different release channels.

10.4. INSTALLER-PROVISIONED POST-INSTALLATION CONFIGURATION

After successfully deploying an installer-provisioned cluster, consider the following post-installation procedures.

10.4.1. Configuring NTP for disconnected clusters (optional)

OpenShift Container Platform installs the **chrony** Network Time Protocol (NTP) service on the cluster nodes. Use the following procedure to configure NTP servers on the control plane nodes and configure worker nodes as NTP clients of the control plane nodes after a successful deployment.

OpenShift Container Platform nodes must agree on a date and time to run properly. When worker nodes retrieve the date and time from the NTP servers on the control plane nodes, it enables the installation and operation of clusters that are not connected to a routable network and thereby do not have access to a higher stratum NTP server.

Procedure

1. Create a Butane config, **99-master-chrony-conf-override.bu**, including the contents of the **chrony.conf** file for the control plane nodes.

**NOTE**

See "Creating machine configs with Butane" for information about Butane.

Butane config example

```

variant: openshift
version: 4.9.0
metadata:
  name: 99-master-chrony-conf-override
  labels:
    machineconfiguration.openshift.io/role: master
storage:
files:
  - path: /etc/chrony.conf
    mode: 0644
    overwrite: true
    contents:
      inline: |
        # Use public servers from the pool.ntp.org project.
        # Please consider joining the pool (https://www.pool.ntp.org/join.html).

        # The Machine Config Operator manages this file
server openshift-master-0.<cluster-name>.<domain> iburst ①
server openshift-master-1.<cluster-name>.<domain> iburst
server openshift-master-2.<cluster-name>.<domain> iburst

stratumweight 0
driftfile /var/lib/chrony/drift
rtcsync
makestep 10 3
bindcmdaddress 127.0.0.1
bindcmdaddress ::1
keyfile /etc/chrony.keys
commandkey 1
generatecommandkey
noclientlog
logchange 0.5
logdir /var/log/chrony

# Configure the control plane nodes to serve as local NTP servers
# for all worker nodes, even if they are not in sync with an
# upstream NTP server.

# Allow NTP client access from the local network.
allow all
# Serve time even if not synchronized to a time source.
local stratum 3 orphan

```

- 1 You must replace **<cluster-name>** with the name of the cluster and replace **<domain>** with the fully qualified domain name.

2. Use Butane to generate a **MachineConfig** object file, **99-master-chrony-conf-override.yaml**, containing the configuration to be delivered to the control plane nodes:

```
$ butane 99-master-chrony-conf-override.bu -o 99-master-chrony-conf-override.yaml
```

3. Create a Butane config, **99-worker-chrony-conf-override.bu**, including the contents of the **chrony.conf** file for the worker nodes that references the NTP servers on the control plane nodes.

Butane config example

```
variant: openshift
version: 4.9.0
metadata:
  name: 99-worker-chrony-conf-override
  labels:
    machineconfiguration.openshift.io/role: worker
storage:
  files:
    - path: /etc/chrony.conf
      mode: 0644
      overwrite: true
      contents:
        inline: |
          # The Machine Config Operator manages this file.
          server openshift-master-0.<cluster-name>.<domain> iburst ①
          server openshift-master-1.<cluster-name>.<domain> iburst
          server openshift-master-2.<cluster-name>.<domain> iburst

          stratumweight 0
          driftfile /var/lib/chrony/drift
          rtcsync
          makestep 10 3
          bindcmdaddress 127.0.0.1
          bindcmdaddress ::1
          keyfile /etc/chrony.keys
          commandkey 1
          generatecommandkey
          noclientlog
          logchange 0.5
          logdir /var/log/chrony
```

- ① You must replace **<cluster-name>** with the name of the cluster and replace **<domain>** with the fully qualified domain name.

4. Use Butane to generate a **MachineConfig** object file, **99-worker-chrony-conf-override.yaml**, containing the configuration to be delivered to the worker nodes:

```
$ butane 99-worker-chrony-conf-override.bu -o 99-worker-chrony-conf-override.yaml
```

5. Apply the **99-master-chrony-conf-override.yaml** policy to the control plane nodes.

```
$ oc apply -f 99-worker-chrony-conf-override.yaml
```

Example output

machineconfig.machineconfiguration.openshift.io/99-master-chrony-conf-override created

6. Apply the **99-worker-chrony-conf-override.yaml** policy to the worker nodes.

\$ oc apply -f 99-worker-chrony-conf-override.yaml

Example output

machineconfig.machineconfiguration.openshift.io/99-worker-chrony-conf-override created

7. Check the status of the applied NTP settings.

\$ oc describe machineconfigpool

10.4.2. Enabling a provisioning network after installation

The assisted installer and installer-provisioned installation for bare metal clusters provide the ability to deploy a cluster without a **provisioning** network. This capability is for scenarios such as proof-of-concept clusters or deploying exclusively with Redfish virtual media when each node's baseboard management controller is routable via the **baremetal** network.

You can enable a **provisioning** network after installation using the Cluster Baremetal Operator (CBO).

Prerequisites

- A dedicated physical network must exist, connected to all worker and control plane nodes.
- You must isolate the native, untagged physical network.
- The network cannot have a DHCP server when the **provisioningNetwork** configuration setting is set to **Managed**.
- You can omit the **provisioningInterface** setting in OpenShift Container Platform 4.9 to use the **bootMACAddress** configuration setting.

Procedure

1. When setting the **provisioningInterface** setting, first identify the provisioning interface name for the cluster nodes. For example, **eth0** or **eno1**.
2. Enable the Preboot eXecution Environment (PXE) on the **provisioning** network interface of the cluster nodes.
3. Retrieve the current state of the **provisioning** network and save it to a provisioning custom resource (CR) file:

\$ oc get provisioning -o yaml > enable-provisioning-nw.yaml

4. Modify the provisioning CR file:

\$ vim ~/enable-provisioning-nw.yaml

Scroll down to the **provisioningNetwork** configuration setting and change it from **Disabled** to

Managed. Then, add the `provisioningOSDownloadURL`, `provisioningIP`, `provisioningNetworkCIDR`, `provisioningDHCPRange`, `provisioningInterface`, and `watchAllNameSpaces` configuration settings after the `provisioningNetwork` setting. Provide appropriate values for each setting.

```
apiVersion: v1
items:
- apiVersion: metal3.io/v1alpha1
  kind: Provisioning
  metadata:
    name: provisioning-configuration
  spec:
    provisioningNetwork: ①
    provisioningOSDownloadURL: ②
    provisioningIP: ③
    provisioningNetworkCIDR: ④
    provisioningDHCPRange: ⑤
    provisioningInterface: ⑥
    watchAllNameSpaces: ⑦
```

- ① The `provisioningNetwork` is one of **Managed**, **Unmanaged**, or **Disabled**. When set to **Managed**, Metal3 manages the provisioning network and the CBO deploys the Metal3 pod with a configured DHCP server. When set to **Unmanaged**, the system administrator configures the DHCP server manually.
- ② The `provisioningOSDownloadURL` is a valid HTTPS URL with a valid sha256 checksum that enables the Metal3 pod to download a qcow2 operating system image ending in `.qcow2.gz` or `.qcow2.xz`. This field is required whether the provisioning network is **Managed**, **Unmanaged**, or **Disabled**. For example:
`http://192.168.0.1/images/rhcos-<version>.x86_64.qcow2.gz?sha256=<sha>`.
- ③ The `provisioningIP` is the static IP address that the DHCP server and ironic use to provision the network. This static IP address must be within the `provisioning` subnet, and outside of the DHCP range. If you configure this setting, it must have a valid IP address even if the `provisioning` network is **Disabled**. The static IP address is bound to the metal3 pod. If the metal3 pod fails and moves to another server, the static IP address also moves to the new server.
- ④ The Classless Inter-Domain Routing (CIDR) address. If you configure this setting, it must have a valid CIDR address even if the `provisioning` network is **Disabled**. For example:
192.168.0.1/24.
- ⑤ The DHCP range. This setting is only applicable to a **Managed** provisioning network. Omit this configuration setting if the `provisioning` network is **Disabled**. For example:
192.168.0.64, 192.168.0.253.
- ⑥ The NIC name for the `provisioning` interface on cluster nodes. The `provisioningInterface` setting is only applicable to **Managed** and **Unmanaged** provisioning networks. Omit the `provisioningInterface` configuration setting if the `provisioning` network is **Disabled**. Omit the `provisioningInterface` configuration setting to use the `bootMACAddress` configuration setting instead.
- ⑦ Set this setting to **true** if you want metal3 to watch namespaces other than the default `openshift-machine-api` namespace. The default value is **false**.

5. Save the changes to the provisioning CR file.

6. Apply the provisioning CR file to the cluster:

```
$ oc apply -f enable-provisioning-nw.yaml
```

10.4.3. Configuring an external load balancer

You can configure an OpenShift Container Platform cluster to use an external load balancer in place of the default load balancer.

Prerequisites

- On your load balancer, TCP over ports 6443, 443, and 80 must be available to any users of your system.
- Load balance the API port, 6443, between each of the control plane nodes.
- Load balance the application ports, 443 and 80, between all of the compute nodes.
- On your load balancer, port 22623, which is used to serve ignition start-up configurations to nodes, is not exposed outside of the cluster.
- Your load balancer must be able to access every machine in your cluster. Methods to allow this access include:
 - Attaching the load balancer to the cluster’s machine subnet.
 - Attaching floating IP addresses to machines that use the load balancer.

IMPORTANT

External load balancing services and the control plane nodes must run on the same L2 network, and on the same VLAN when using VLANs to route traffic between the load balancing services and the control plane nodes.

Procedure

1. Enable access to the cluster from your load balancer on ports 6443, 443, and 80.

As an example, note this HAProxy configuration:

A section of a sample HAProxy configuration

```
...
listen my-cluster-api-6443
bind 0.0.0.0:6443
mode tcp
balance roundrobin
server my-cluster-master-2 192.0.2.2:6443 check
server my-cluster-master-0 192.0.2.3:6443 check
server my-cluster-master-1 192.0.2.1:6443 check
listen my-cluster-apps-443
bind 0.0.0.0:443
mode tcp
balance roundrobin
```

```

server my-cluster-worker-0 192.0.2.6:443 check
server my-cluster-worker-1 192.0.2.5:443 check
server my-cluster-worker-2 192.0.2.4:443 check
listen my-cluster-apps-80
bind 0.0.0.0:80
mode tcp
balance roundrobin
server my-cluster-worker-0 192.0.2.7:80 check
server my-cluster-worker-1 192.0.2.9:80 check
server my-cluster-worker-2 192.0.2.8:80 check

```

2. Add records to your DNS server for the cluster API and apps over the load balancer. For example:

```

<load_balancer_ip_address> api.<cluster_name>.<base_domain>
<load_balancer_ip_address> apps.<cluster_name>.<base_domain>

```

3. From a command line, use **curl** to verify that the external load balancer and DNS configuration are operational.

- a. Verify that the cluster API is accessible:

```
$ curl https://<loadbalancer_ip_address>:6443/version --insecure
```

If the configuration is correct, you receive a JSON object in response:

```
{
  "major": "1",
  "minor": "11+",
  "gitVersion": "v1.11.0+ad103ed",
  "gitCommit": "ad103ed",
  "gitTreeState": "clean",
  "buildDate": "2019-01-09T06:44:10Z",
  "goVersion": "go1.10.3",
  "compiler": "gc",
  "platform": "linux/amd64"
}
```

- b. Verify that cluster applications are accessible:

NOTE

You can also verify application accessibility by opening the OpenShift Container Platform console in a web browser.

```
$ curl http://console-openshift-console.apps.<cluster_name>.<base_domain> -I -L --insecure
```

If the configuration is correct, you receive an HTTP response:

```

HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.<cluster-name>.<base domain>/
```

```

cache-control: no-cacheHTTP/1.1 200 OK

```

10.5. EXPANDING THE CLUSTER

After deploying an installer-provisioned OpenShift Container Platform cluster, you can use the following procedures to expand the number of worker nodes. Ensure that each prospective worker node meets the prerequisites.

NOTE

Expanding the cluster using RedFish Virtual Media involves meeting minimum firmware requirements. See **Firmware requirements for installing with virtual media** in the **Prerequisites** section for additional details when expanding the cluster using RedFish Virtual Media.

10.5.1. Preparing the bare metal node

Expanding the cluster requires a DHCP server. Each node must have a DHCP reservation.

RESERVING IP ADDRESSES SO THEY BECOME STATIC IP ADDRESSES

Some administrators prefer to use static IP addresses so that each node's IP address remains constant in the absence of a DHCP server. To use static IP addresses in the OpenShift Container Platform cluster, **reserve the IP addresses in the DHCP server with an infinite lease**. After the installer provisions the node successfully, the dispatcher script will check the node's network configuration. If the dispatcher script finds that the network configuration contains a DHCP infinite lease, it will recreate the connection as a static IP connection using the IP address from the DHCP infinite lease. NICs without DHCP infinite leases will remain unmodified.

Preparing the bare metal node requires executing the following procedure from the provisioner node.

Procedure

- Get the **oc** binary, if needed. It should already exist on the provisioner node.

```
[kni@provisioner ~]$ curl -s https://mirror.openshift.com/pub/openshift-
v4/clients/ocp/$VERSION/openshift-client-linux-$VERSION.tar.gz | tar zxvf - oc
```

```
[kni@provisioner ~]$ sudo cp oc /usr/local/bin
```

2. Power off the bare metal node via the baseboard management controller and ensure it is off.
3. Retrieve the user name and password of the bare metal node's baseboard management controller. Then, create **base64** strings from the user name and password. In the following example, the user name is **root** and the password is **calvin**.

```
[kni@provisioner ~]$ echo -ne "root" | base64
```

```
[kni@provisioner ~]$ echo -ne "calvin" | base64
```

4. Create a configuration file for the bare metal node.

```
[kni@provisioner ~]$ vim bmh.yaml
```

```
---
apiVersion: v1
kind: Secret
metadata:
  name: openshift-worker-<num>-bmc-secret
type: Opaque
data:
  username: <base64-of-uid>
  password: <base64-of-pwd>
---
apiVersion: metal3.io/v1alpha1
kind: BareMetalHost
metadata:
  name: openshift-worker-<num>
spec:
  online: true
  bootMACAddress: <NIC1-mac-address>
  bmc:
    address: <protocol>://<bmc-ip>
    credentialsName: openshift-worker-<num>-bmc-secret
```

Replace **<num>** for the worker number of the bare metal node in the two **name** fields and the **credentialsName** field. Replace **<base64-of-uid>** with the **base64** string of the user name. Replace **<base64-of-pwd>** with the **base64** string of the password. Replace **<NIC1-mac-address>** with the MAC address of the bare metal node's first NIC.

See the BMC addressing section for additional BMC configuration options. Replace **<protocol>** with the BMC protocol, such as IPMI, RedFish, or others. Replace **<bmc-ip>** with the IP address of the bare metal node's baseboard management controller.

NOTE

If the MAC address of an existing bare metal node matches the MAC address of a bare metal host that you are attempting to provision, then the Ironic installation will fail. If the host enrollment, inspection, cleaning, or other Ironic steps fail, the Bare Metal Operator retries the installation continuously. See [Diagnosing a host duplicate MAC address](#) for more information.

5. Create the bare metal node.

```
[kni@provisioner ~]$ oc -n openshift-machine-api create -f bmh.yaml
secret/openshift-worker-<num>-bmc-secret created
baremetalhost.metal3.io/openshift-worker-<num> created
```

Where <num> will be the worker number.

6. Power up and inspect the bare metal node.

```
[kni@provisioner ~]$ oc -n openshift-machine-api get bmh openshift-worker-<num>
```

Where <num> is the worker node number.

NAME	STATUS	PROVISIONING STATUS	CONSUMER	BMC
HARDWARE PROFILE	ONLINE	ERROR		
openshift-worker-<num>	OK	ready	ipmi://<out-of-band-ip>	unknown
true				

10.5.2. Preparing to deploy with Virtual Media on the baremetal network

If the **provisioning** network is enabled and you want to expand the cluster using Virtual Media on the **baremetal** network, use the following procedure.

Prerequisites

- There is an existing cluster with a **baremetal** network and a **provisioning** network.

Procedure

1. Edit the **provisioning** custom resource (CR) to enable deploying with Virtual Media on the **baremetal** network:

```
oc edit provisioning

apiVersion: metal3.io/v1alpha1
kind: Provisioning
metadata:
  creationTimestamp: "2021-08-05T18:51:50Z"
  finalizers:
  - provisioning.metal3.io
  generation: 8
  name: provisioning-configuration
  resourceVersion: "551591"
  uid: f76e956f-24c6-4361-aa5b-feaf72c5b526
spec:
  preProvisioningOSDownloadURLs: {}
  provisioningDHCPRange: 172.22.0.10,172.22.0.254
  provisioningIP: 172.22.0.3
  provisioningInterface: enp1s0
  provisioningNetwork: Managed
  provisioningNetworkCIDR: 172.22.0.0/24
```

```

provisioningOSDownloadURL: http://192.168.111.1/images/rhcos-
<version>.x86_64.qcow2.gz?sha256=<sha256>
  virtualMediaViaExternalNetwork: true 1
status:
generations:
- group: apps
  hash: ""
  lastGeneration: 7
  name: metal3
  namespace: openshift-machine-api
  resource: deployments
- group: apps
  hash: ""
  lastGeneration: 1
  name: metal3-image-cache
  namespace: openshift-machine-api
  resource: daemonsets
  observedGeneration: 8
  readyReplicas: 0

```

1 Add **virtualMediaViaExternalNetwork: true** to the **provisioning** CR.

2. Edit the machineset to use the API VIP address:

```
oc edit machineset
```

```

apiVersion: machine.openshift.io/v1beta1
kind: MachineSet
metadata:
  creationTimestamp: "2021-08-05T18:51:52Z"
  generation: 11
  labels:
    machine.openshift.io/cluster-api-cluster: ostest-hwmdt
    machine.openshift.io/cluster-api-machine-role: worker
    machine.openshift.io/cluster-api-machine-type: worker
  name: ostest-hwmdt-worker-0
  namespace: openshift-machine-api
  resourceVersion: "551513"
  uid: fad1c6e0-b9da-4d4a-8d73-286f78788931
spec:
  replicas: 2
  selector:
    matchLabels:
      machine.openshift.io/cluster-api-cluster: ostest-hwmdt
      machine.openshift.io/cluster-api-machineset: ostest-hwmdt-worker-0
  template:
    metadata:
      labels:
        machine.openshift.io/cluster-api-cluster: ostest-hwmdt
        machine.openshift.io/cluster-api-machine-role: worker
        machine.openshift.io/cluster-api-machine-type: worker
        machine.openshift.io/cluster-api-machineset: ostest-hwmdt-worker-0
    spec:
      metadata: {}

```

```

providerSpec:
  value:
    apiVersion: baremetal.cluster.k8s.io/v1alpha1
    hostSelector: {}
    image:
      checksum: http://172.22.0.3:6181/images/rhcos-<version>.x86_64.qcow2.<md5sum>
1
      url: http://172.22.0.3:6181/images/rhcos-<version>.x86_64.qcow2 2
    kind: BareMetalMachineProviderSpec
    metadata:
      creationTimestamp: null
    userData:
      name: worker-user-data
  status:
    availableReplicas: 2
    fullyLabeledReplicas: 2
    observedGeneration: 11
    readyReplicas: 2
    replicas: 2

```

- 1 Edit the **checksum** URL to use the API VIP address.
- 2 Edit the **url** URL to use the API VIP address.

10.5.3. Diagnosing a duplicate MAC address when provisioning a new host in the cluster

If the MAC address of an existing bare-metal node in the cluster matches the MAC address of a bare-metal host you are attempting to add to the cluster, the Bare Metal Operator associates the host with the existing node. If the host enrollment, inspection, cleaning, or other Ironic steps fail, the Bare Metal Operator retries the installation continuously. A registration error is displayed for the failed bare-metal host.

You can diagnose a duplicate MAC address by examining the bare-metal hosts that are running in the **openshift-machine-api** namespace.

Prerequisites

- Install an OpenShift Container Platform cluster on bare metal.
- Install the OpenShift Container Platform CLI **oc**.
- Log in as a user with **cluster-admin** privileges.

Procedure

To determine whether a bare-metal host that fails provisioning has the same MAC address as an existing node, do the following:

1. Get the bare-metal hosts running in the **openshift-machine-api** namespace:

```
$ oc get bmh -n openshift-machine-api
```

Example output

NAME	STATUS	PROVISIONING STATUS	CONSUMER
openshift-master-0	OK	externally provisioned	openshift-zpwpq-master-0
openshift-master-1	OK	externally provisioned	openshift-zpwpq-master-1
openshift-master-2	OK	externally provisioned	openshift-zpwpq-master-2
openshift-worker-0	OK	provisioned	openshift-zpwpq-worker-0-lv84n
openshift-worker-1	OK	provisioned	openshift-zpwpq-worker-0-zd8lm
openshift-worker-2	error	registering	

2. To see more detailed information about the status of the failing host, run the following command replacing <bare_metal_host_name> with the name of the host:

```
$ oc get -n openshift-machine-api bmh <bare_metal_host_name> -o yaml
```

Example output

```
...
status:
  errorCount: 12
  errorMessage: MAC address b4:96:91:1d:7c:20 conflicts with existing node openshift-worker-1
  errorType: registration error
...
...
```

10.5.4. Provisioning the bare metal node

Provisioning the bare metal node requires executing the following procedure from the provisioner node.

Procedure

1. Ensure the **PROVISIONING STATUS** is **ready** before provisioning the bare metal node.

```
$ oc -n openshift-machine-api get bmh openshift-worker-<num>
```

Where <num> is the worker node number.

NAME	STATUS	PROVISIONING STATUS	CONSUMER	BMC
HARDWARE PROFILE	ONLINE	ERROR		
openshift-worker-<num>	OK	ready		ipmi://<out-of-band-ip> unknown
	true			

2. Get a count of the number of worker nodes.

```
$ oc get nodes
```

NAME	STATUS	ROLES	AGE	VERSION
provisioner.openshift.example.com	Ready	master	30h	v1.22.1
openshift-master-1.openshift.example.com	Ready	master	30h	v1.22.1
openshift-master-2.openshift.example.com	Ready	master	30h	v1.22.1
openshift-master-3.openshift.example.com	Ready	master	30h	v1.22.1
openshift-worker-0.openshift.example.com	Ready	master	30h	v1.22.1
openshift-worker-1.openshift.example.com	Ready	master	30h	v1.22.1

- Get the machine set.

```
$ oc get machinesets -n openshift-machine-api
```

NAME	DESIRED	CURRENT	READY	AVAILABLE	AGE
...					
openshift-worker-0.example.com	1	1	1	1	55m
openshift-worker-1.example.com	1	1	1	1	55m

- Increase the number of worker nodes by one.

```
$ oc scale --replicas=<num> machineset <machineset> -n openshift-machine-api
```

Replace **<num>** with the new number of worker nodes. Replace **<machineset>** with the name of the machine set from the previous step.

- Check the status of the bare metal node.

```
$ oc -n openshift-machine-api get bmh openshift-worker-<num>
```

Where **<num>** is the worker node number. The status changes from **ready** to **provisioning**.

NAME	STATUS	PROVISIONING STATUS	CONSUMER	BMC
HARDWARE PROFILE	ONLINE	ERROR		
openshift-worker-<num>	OK	provisioning	openshift-worker-<num>-65tjz	
ipmi://<out-of-band-ip>	unknown	true		

The **provisioning** status remains until the OpenShift Container Platform cluster provisions the node. This can take 30 minutes or more. After the node is provisioned, the status will change to **provisioned**.

NAME	STATUS	PROVISIONING STATUS	CONSUMER	BMC
HARDWARE PROFILE	ONLINE	ERROR		
openshift-worker-<num>	OK	provisioned	openshift-worker-<num>-65tjz	
ipmi://<out-of-band-ip>	unknown	true		

- After provisioning completes, ensure the bare metal node is ready.

```
$ oc get nodes
```

NAME	STATUS	ROLES	AGE	VERSION
provisioner.openshift.example.com	Ready	master	30h	v1.22.1
openshift-master-1.openshift.example.com	Ready	master	30h	v1.22.1
openshift-master-2.openshift.example.com	Ready	master	30h	v1.22.1
openshift-master-3.openshift.example.com	Ready	master	30h	v1.22.1
openshift-worker-0.openshift.example.com	Ready	master	30h	v1.22.1
openshift-worker-1.openshift.example.com	Ready	master	30h	v1.22.1
openshift-worker-<num>.openshift.example.com	Ready	worker	3m27s	v1.22.1

You can also check the kubelet.

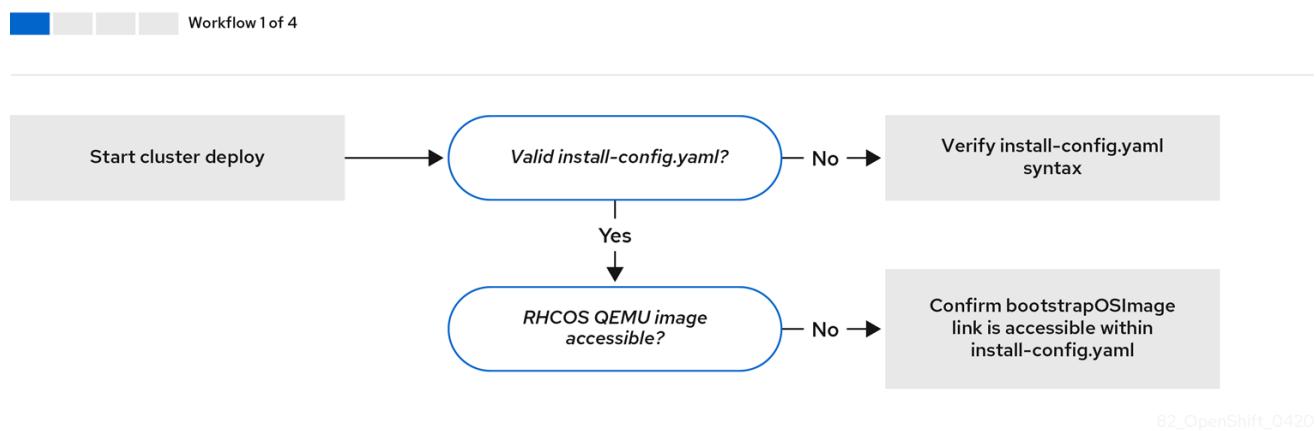

```
$ ssh openshift-worker-<num>
```

```
[kni@openshift-worker-<num>]$ journalctl -fu kubelet
```

10.6. TROUBLESHOOTING

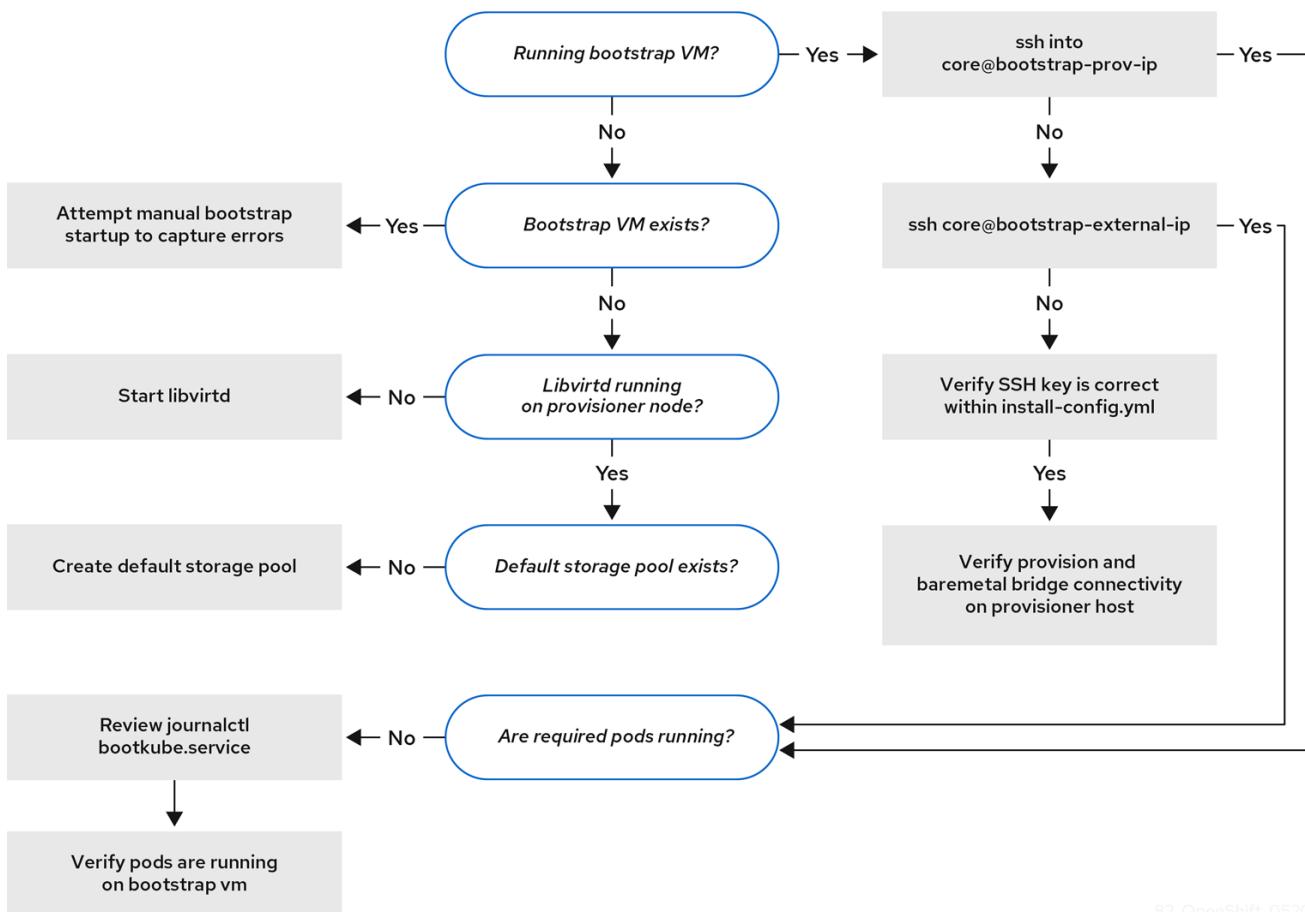

10.6.1. Troubleshooting the installer workflow

Prior to troubleshooting the installation environment, it is critical to understand the overall flow of the installer-provisioned installation on bare metal. The diagrams below provide a troubleshooting flow with a step-by-step breakdown for the environment.

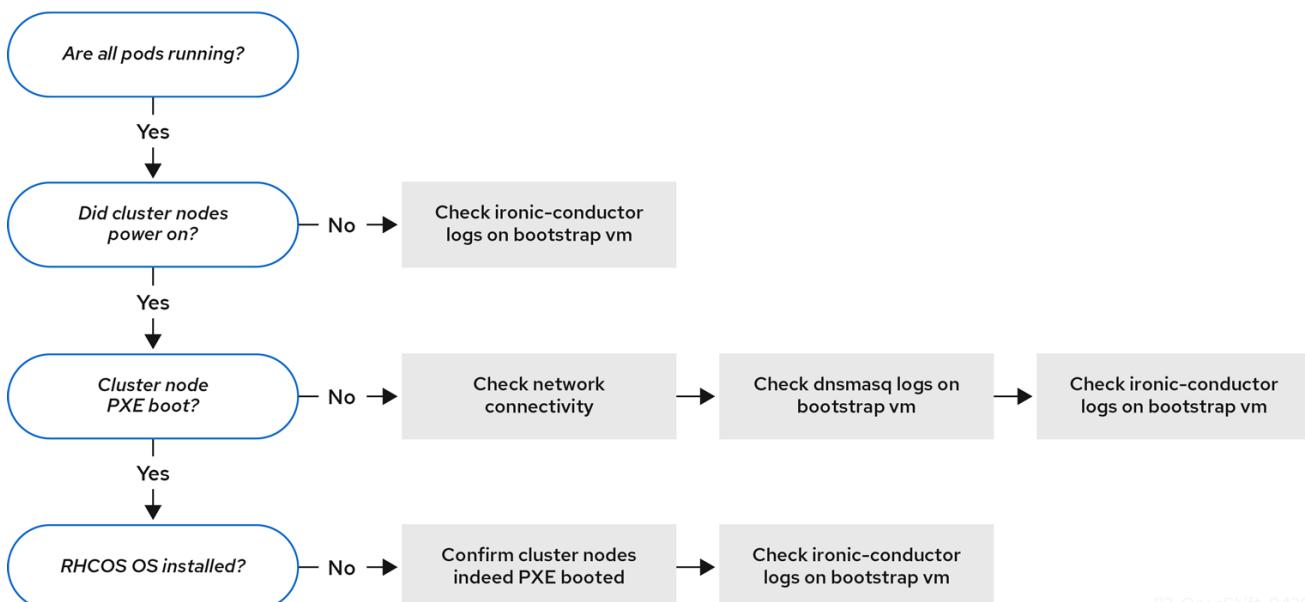

82_OpenShift_0420

Workflow 1 of 4 illustrates a troubleshooting workflow when the **install-config.yaml** file has errors or the Red Hat Enterprise Linux CoreOS (RHCOS) images are inaccessible. Troubleshooting suggestions can be found at [Troubleshooting **Install-config.yaml**](#).

█ Workflow 2 of 4

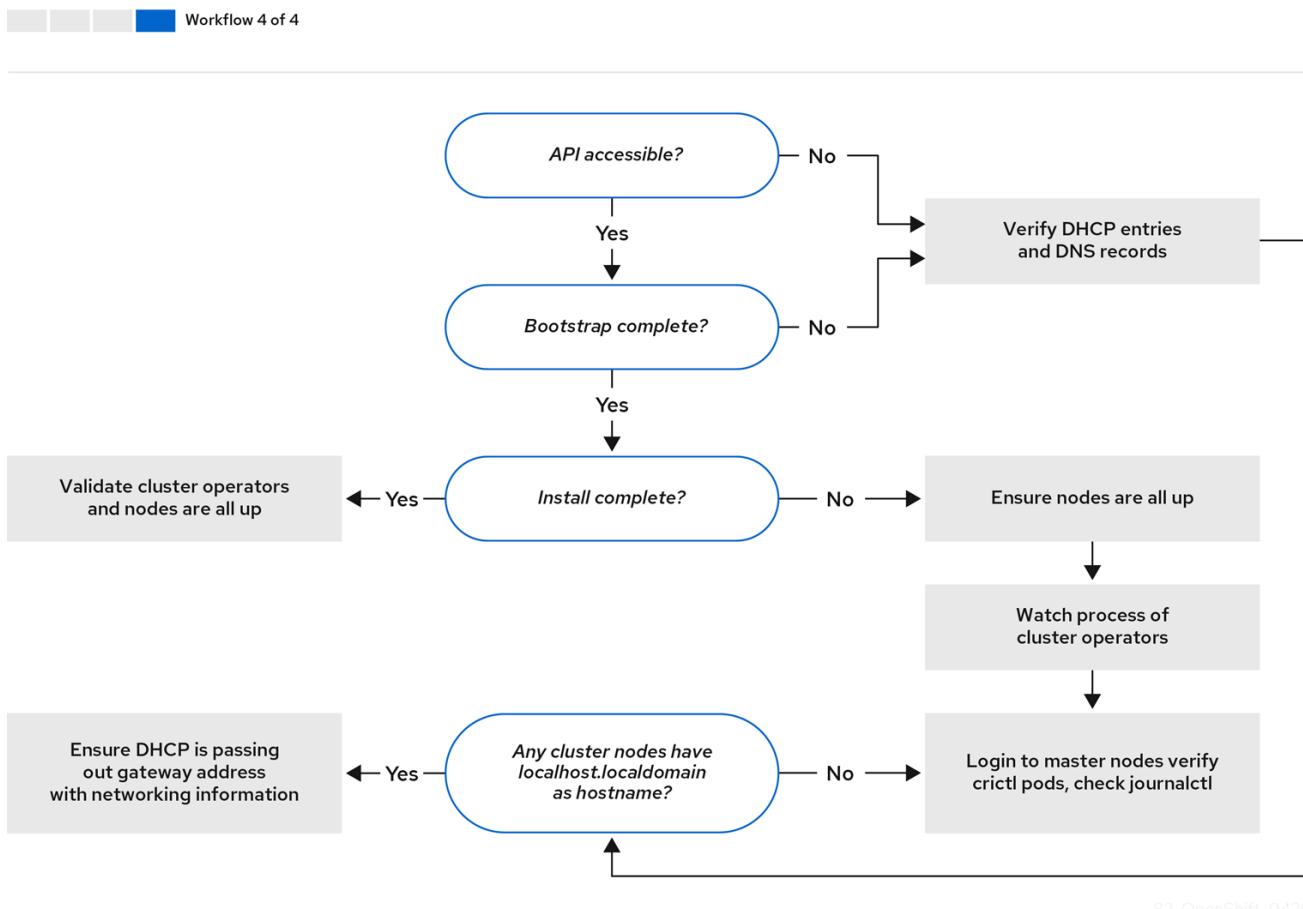

82_OpenShift_0520

Workflow 2 of 4 illustrates a troubleshooting workflow for [bootstrap VM issues](#), [bootstrap VMs that cannot boot up the cluster nodes](#), and [inspecting logs](#). When installing a OpenShift Container Platform cluster without the **provisioning** network, this workflow does not apply.

█ Workflow 3 of 4

82_OpenShift_0420

Workflow 3 of 4 illustrates a troubleshooting workflow for [cluster nodes that will not PXE boot](#). If installing using RedFish Virtual Media, each node must meet minimum firmware requirements for the installer to deploy the node. See [Firmware requirements for installing with virtual media](#) in the [Prerequisites](#) section for additional details.

82_OpenShift_0420

Workflow 4 of 4 illustrates a troubleshooting workflow from [a non-accessible API](#) to a [validated installation](#).

10.6.2. Troubleshooting `install-config.yaml`

The **install-config.yaml** configuration file represents all of the nodes that are part of the OpenShift Container Platform cluster. The file contains the necessary options consisting of but not limited to **apiVersion**, **baseDomain**, **imageContentSources** and virtual IP addresses. If errors occur early in the deployment of the OpenShift Container Platform cluster, the errors are likely in the **install-config.yaml** configuration file.

Procedure

1. Use the guidelines in [YAML-tips](#).
2. Verify the YAML syntax is correct using [syntax-check](#).
3. Verify the Red Hat Enterprise Linux CoreOS (RHCOS) QEMU images are properly defined and accessible via the URL provided in the **install-config.yaml**. For example:

```
$ curl -s -o /dev/null -I -w "%{http_code}\n" http://webserver.example.com:8080/rhcos-44.81.202004250133-0-qemu.x86_64.qcow2.gz?
sha256=7d884b46ee54fe87bbc3893bf2aa99af3b2d31f2e19ab5529c60636fb0f1ce7
```

If the output is **200**, there is a valid response from the webserver storing the bootstrap VM image.

10.6.3. Bootstrap VM issues

The OpenShift Container Platform installer spawns a bootstrap node virtual machine, which handles provisioning the OpenShift Container Platform cluster nodes.

Procedure

1. About 10 to 15 minutes after triggering the installer, check to ensure the bootstrap VM is operational using the **virsh** command:

```
$ sudo virsh list
```

Id	Name	State
12	openshift-xf6fq-bootstrap	running

NOTE

The name of the bootstrap VM is always the cluster name followed by a random set of characters and ending in the word "bootstrap."

If the bootstrap VM is not running after 10-15 minutes, troubleshoot why it is not running. Possible issues include:

2. Verify **libvirdt** is running on the system:

```
$ systemctl status libvirdt
```

- libvirdt.service - Virtualization daemon

Loaded: loaded (/usr/lib/systemd/system/libvirdt.service; enabled; vendor preset: enabled)

Active: active (running) since Tue 2020-03-03 21:21:07 UTC; 3 weeks 5 days ago

Docs: man:libvirdt(8)

https://libvirt.org

Main PID: 9850 (libvirdt)

Tasks: 20 (limit: 32768)

Memory: 74.8M

CGroup: /system.slice/libvirdt.service
 └─ 9850 /usr/sbin/libvirdt

If the bootstrap VM is operational, log in to it.

3. Use the **virsh console** command to find the IP address of the bootstrap VM:

```
$ sudo virsh console example.com
```

Connected to domain example.com
Escape character is ^]

```
Red Hat Enterprise Linux CoreOS 43.81.202001142154.0 (Ootpa) 4.3
SSH host key: SHA256:BRWJktXZgQQRY5zjuAV0IKZ4WM7i4TiUyMVanqu9Pqg (ED25519)
SSH host key: SHA256:7+iKGA7VtG5szmk2jB5gl/5EZ+SNCJ3a2g23o0lnlio (ECDSA)
SSH host key: SHA256:DH5VWhvhvagOTaLsYiVNse9ca+ZSW/30OOMed8rlGOc (RSA)
ens3: fd35:919d:4042:2:c7ed:9a9f:a9ec:7
ens4: 172.22.0.2 fe80::1d05:e52e:be5d:263f
localhost login:
```

IMPORTANT

When deploying a OpenShift Container Platform cluster without the **provisioning** network, you must use a public IP address and not a private IP address like **172.22.0.2**.

- After you obtain the IP address, log in to the bootstrap VM using the **ssh** command:

NOTE

In the console output of the previous step, you can use the IPv6 IP address provided by **ens3** or the IPv4 IP provided by **ens4**.

```
$ ssh core@172.22.0.2
```

If you are not successful logging in to the bootstrap VM, you have likely encountered one of the following scenarios:

- You cannot reach the **172.22.0.0/24** network. Verify network connectivity on the provisioner host specifically around the **provisioning** network bridge. This will not be the issue if you are not using the **provisioning** network.
- You cannot reach the bootstrap VM via the public network. When attempting to SSH via **baremetal** network, verify connectivity on the **provisioner** host specifically around the **baremetal** network bridge.
- You encountered **Permission denied (publickey,password,keyboard-interactive)**. When attempting to access the bootstrap VM, a **Permission denied** error might occur. Verify that the SSH key for the user attempting to log into the VM is set within the **install-config.yaml** file.

10.6.3.1. Bootstrap VM cannot boot up the cluster nodes

During the deployment, it is possible for the bootstrap VM to fail to boot the cluster nodes, which prevents the VM from provisioning the nodes with the RHCOS image. This scenario can arise due to:

- A problem with the **install-config.yaml** file.
- Issues with out-of-band network access via the baremetal network.

To verify the issue, there are three containers related to **ironic**:

- ironic-api**

- **ironic-conductor**
- **ironic-inspector**

Procedure

1. Log in to the bootstrap VM:

```
$ ssh core@172.22.0.2
```

2. To check the container logs, execute the following:

```
[core@localhost ~]$ sudo podman logs -f <container-name>
```

Replace **<container-name>** with one of **ironic-api**, **ironic-conductor**, or **ironic-inspector**. If you encounter an issue where the control plane nodes are not booting up via PXE, check the **ironic-conductor** pod. The **ironic-conductor** pod contains the most detail about the attempt to boot the cluster nodes, because it attempts to log in to the node over IPMI.

Potential reason

The cluster nodes might be in the **ON** state when deployment started.

Solution

Power off the OpenShift Container Platform cluster nodes before you begin the installation over IPMI:

```
$ ipmitool -I lanplus -U root -P <password> -H <out-of-band-ip> power off
```

10.6.3.2. Inspecting logs

When experiencing issues downloading or accessing the RHCOS images, first verify that the URL is correct in the **install-config.yaml** configuration file.

Example of internal webserver hosting RHCOS images

```
bootstrapOSImage: http://<ip:port>/rhcos-43.81.202001142154.0-qemu.x86_64.qcow2.gz?  
sha256=9d999f55ff1d44f7ed7c106508e5deecd04dc3c06095d34d36bf1cd127837e0c  
clusterOSImage: http://<ip:port>/rhcos-43.81.202001142154.0-openstack.x86_64.qcow2.gz?  
sha256=a1bda656fa0892f7b936fdc6b6a6086bddaed5dafacedcd7a1e811abb78fe3b0
```

The **ipa-downloader** and **coreos-downloader** containers download resources from a webserver or the external [quay.io](#) registry, whichever the **install-config.yaml** configuration file specifies. Verify the following two containers are up and running and inspect their logs as needed:

- **ipa-downloader**
- **coreos-downloader**

Procedure

1. Log in to the bootstrap VM:

```
$ ssh core@172.22.0.2
```

- Check the status of the **ipa-downloader** and **coreos-downloader** containers within the bootstrap VM:

```
[core@localhost ~]$ sudo podman logs -f ipa-downloader
```

```
[core@localhost ~]$ sudo podman logs -f coreos-downloader
```

If the bootstrap VM cannot access the URL to the images, use the **curl** command to verify that the VM can access the images.

- To inspect the **bootkube** logs that indicate if all the containers launched during the deployment phase, execute the following:

```
[core@localhost ~]$ journalctl -xe
```

```
[core@localhost ~]$ journalctl -b -f -u bootkube.service
```

- Verify all the pods, including **dnsmasq**, **mariadb**, **httpd**, and **ironic**, are running:

```
[core@localhost ~]$ sudo podman ps
```

- If there are issues with the pods, check the logs of the containers with issues. To check the log of the **ironic-api**, execute the following:

```
[core@localhost ~]$ sudo podman logs <ironic-api>
```

10.6.4. Cluster nodes will not PXE boot

When OpenShift Container Platform cluster nodes will not PXE boot, execute the following checks on the cluster nodes that will not PXE boot. This procedure does not apply when installing a OpenShift Container Platform cluster without the **provisioning** network.

Procedure

- Check the network connectivity to the **provisioning** network.
- Ensure PXE is enabled on the NIC for the **provisioning** network and PXE is disabled for all other NICs.
- Verify that the **install-config.yaml** configuration file has the proper hardware profile and boot MAC address for the NIC connected to the **provisioning** network. For example:

control plane node settings

```
bootMACAddress: 24:6E:96:1B:96:90 # MAC of bootable provisioning NIC
hardwareProfile: default      #control plane node settings
```

Worker node settings

```
bootMACAddress: 24:6E:96:1B:96:90 # MAC of bootable provisioning NIC
hardwareProfile: unknown      #worker node settings
```

10.6.5. The API is not accessible

When the cluster is running and clients cannot access the API, domain name resolution issues might impede access to the API.

Procedure

1. **Hostname Resolution:** Check the cluster nodes to ensure they have a fully qualified domain name, and not just **localhost.localdomain**. For example:

```
$ hostname
```

If a hostname is not set, set the correct hostname. For example:

```
$ hostnamectl set-hostname <hostname>
```

2. **Incorrect Name Resolution:** Ensure that each node has the correct name resolution in the DNS server using **dig** and **nslookup**. For example:

```
$ dig api.<cluster-name>.example.com
```

```
; <>> DiG 9.11.4-P2-RedHat-9.11.4-26.P2.el8 <>> api.<cluster-name>.example.com
;; global options: +cmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 37551
;; flags: qr aa rd ra; QUERY: 1, ANSWER: 1, AUTHORITY: 1, ADDITIONAL: 2

;; OPT PSEUDOSECTION:

;; MSG SIZE rcvd: 140
```

The output in the foregoing example indicates that the appropriate IP address for the **api.<cluster-name>.example.com** VIP is **10.19.13.86**. This IP address should reside on the **baremetal** network.

10.6.6. Cleaning up previous installations

In the event of a previous failed deployment, remove the artifacts from the failed attempt before attempting to deploy OpenShift Container Platform again.

Procedure

- Power off all bare metal nodes prior to installing the OpenShift Container Platform cluster:

```
$ ipmitool -I lanplus -U <user> -P <password> -H <management-server-ip> power off
```

- Remove all old bootstrap resources if any are left over from a previous deployment attempt:

```
for i in $(sudo virsh list | tail -n +3 | grep bootstrap | awk {'print $2'});
do
    sudo virsh destroy $i;
    sudo virsh undefine $i;
    sudo virsh vol-delete $i --pool $i;
    sudo virsh vol-delete $i.ign --pool $i;
    sudo virsh pool-destroy $i;
    sudo virsh pool-undefine $i;
done
```

- Remove the following from the **clusterconfigs** directory to prevent Terraform from failing:

```
$ rm -rf ~/clusterconfigs/auth ~/clusterconfigs/terraform* ~/clusterconfigs/tls
~/clusterconfigs/metadata.json
```

10.6.7. Issues with creating the registry

When creating a disconnected registry, you might encounter a "User Not Authorized" error when attempting to mirror the registry. This error might occur if you fail to append the new authentication to the existing **pull-secret.txt** file.

Procedure

- Check to ensure authentication is successful:

```
$ /usr/local/bin/oc adm release mirror \
-a pull-secret-update.json
--from=$UPSTREAM_REPO \
--to-release-image=$LOCAL_REG/$LOCAL_REPO:${VERSION} \
--to=$LOCAL_REG/$LOCAL_REPO
```

NOTE

Example output of the variables used to mirror the install images:

```
UPSTREAM_REPO=${RELEASE_IMAGE}
LOCAL_REG=<registry_FQDN>:<registry_port>
LOCAL_REPO='ocp4/openshift4'
```

The values of **RELEASE_IMAGE** and **VERSION** were set during the **Retrieving OpenShift Installer** step of the **Setting up the environment for an OpenShift installation** section.

- After mirroring the registry, confirm that you can access it in your disconnected environment:

```
$ curl -k -u <user>:<password> https://registry.example.com:<registry-port>/v2/_catalog
{"repositories":["<Repo-Name>"]}
```

10.6.8. Miscellaneous issues

10.6.8.1. Addressing the runtime network not ready error

After the deployment of a cluster you might receive the following error:

```
`runtime network not ready: NetworkReady=false reason:NetworkPluginNotReady message:Network
plugin returns error: Missing CNI default network`
```

The Cluster Network Operator is responsible for deploying the networking components in response to a special object created by the installer. It runs very early in the installation process, after the control plane (master) nodes have come up, but before the bootstrap control plane has been torn down. It can be indicative of more subtle installer issues, such as long delays in bringing up control plane (master) nodes or issues with **apiserver** communication.

Procedure

- Inspect the pods in the **openshift-network-operator** namespace:

NAME	READY STATUS	RESTARTS	AGE
pod/network-operator-69dfd7b577-bg89v	0/1	ContainerCreating	0 149m

- On the **provisioner** node, determine that the network configuration exists:

```
$ kubectl get network.config.openshift.io cluster -oyaml

apiVersion: config.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  serviceNetwork:
  - 172.30.0.0/16
  clusterNetwork:
  - cidr: 10.128.0.0/14
  hostPrefix: 23
  networkType: OpenShiftSDN
```

If it does not exist, the installer did not create it. To determine why the installer did not create it, execute the following:

```
$ openshift-install create manifests
```

- Check that the **network-operator** is running:

```
$ kubectl -n openshift-network-operator get pods
```

4. Retrieve the logs:

```
$ kubectl -n openshift-network-operator logs -l "name=network-operator"
```

On high availability clusters with three or more control plane (master) nodes, the Operator will perform leader election and all other Operators will sleep. For additional details, see [Troubleshooting](#).

10.6.8.2. Cluster nodes not getting the correct IPv6 address over DHCP

If the cluster nodes are not getting the correct IPv6 address over DHCP, check the following:

1. Ensure the reserved IPv6 addresses reside outside the DHCP range.
2. In the IP address reservation on the DHCP server, ensure the reservation specifies the correct DHCP Unique Identifier (DUID). For example:

```
# This is a dnsmasq dhcp reservation, 'id:00:03:00:01' is the client id and '18:db:f2:8c:d5:9f' is
the MAC Address for the NIC
id:00:03:00:01:18:db:f2:8c:d5:9f,openshift-master-1,[2620:52:0:1302::6]
```

3. Ensure that route announcements are working.
4. Ensure that the DHCP server is listening on the required interfaces serving the IP address ranges.

10.6.8.3. Cluster nodes not getting the correct hostname over DHCP

During IPv6 deployment, cluster nodes must get their hostname over DHCP. Sometimes the **NetworkManager** does not assign the hostname immediately. A control plane (master) node might report an error such as:

```
Failed Units: 2
NetworkManager-wait-online.service
nodeip-configuration.service
```

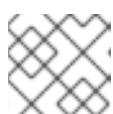

This error indicates that the cluster node likely booted without first receiving a hostname from the DHCP server, which causes **kublet** to boot with a **localhost.localdomain** hostname. To address the error, force the node to renew the hostname.

Procedure

1. Retrieve the **hostname**:

```
[core@master-X ~]$ hostname
```

If the hostname is **localhost**, proceed with the following steps.

NOTE

Where **X** is the control plane node number.

- Force the cluster node to renew the DHCP lease:

```
[core@master-X ~]$ sudo nmcli con up "<bare-metal-nic>"
```

Replace **<bare-metal-nic>** with the wired connection corresponding to the **baremetal** network.

- Check **hostname** again:

```
[core@master-X ~]$ hostname
```

- If the hostname is still **localhost.localdomain**, restart **NetworkManager**:

```
[core@master-X ~]$ sudo systemctl restart NetworkManager
```

- If the hostname is still **localhost.localdomain**, wait a few minutes and check again. If the hostname remains **localhost.localdomain**, repeat the previous steps.

- Restart the **nodeip-configuration** service:

```
[core@master-X ~]$ sudo systemctl restart nodeip-configuration.service
```

This service will reconfigure the **kubelet** service with the correct hostname references.

- Reload the unit files definition since the kubelet changed in the previous step:

```
[core@master-X ~]$ sudo systemctl daemon-reload
```

- Restart the **kubelet** service:

```
[core@master-X ~]$ sudo systemctl restart kubelet.service
```

- Ensure **kubelet** booted with the correct hostname:

```
[core@master-X ~]$ sudo journalctl -fu kubelet.service
```

If the cluster node is not getting the correct hostname over DHCP after the cluster is up and running, such as during a reboot, the cluster will have a pending **csr**. **Do not** approve a **csr**, or other issues might arise.

Addressing a **csr**

- Get CSRs on the cluster:

```
$ oc get csr
```

- Verify if a pending **csr** contains **Subject Name: localhost.localdomain**:

```
$ oc get csr <pending_csr> -o jsonpath='{.spec.request}' | base64 --decode | openssl req -noout -text
```

- Remove any **csr** that contains **Subject Name: localhost.localdomain**:

```
$ oc delete csr <wrong_csr>
```

10.6.8.4. Routes do not reach endpoints

During the installation process, it is possible to encounter a Virtual Router Redundancy Protocol (VRRP) conflict. This conflict might occur if a previously used OpenShift Container Platform node that was once part of a cluster deployment using a specific cluster name is still running but not part of the current OpenShift Container Platform cluster deployment using that same cluster name. For example, a cluster was deployed using the cluster name **openshift**, deploying three control plane (master) nodes and three worker nodes. Later, a separate install uses the same cluster name **openshift**, but this redeployment only installed three control plane (master) nodes, leaving the three worker nodes from a previous deployment in an **ON** state. This might cause a Virtual Router Identifier (VRID) conflict and a VRRP conflict.

1. Get the route:

```
$ oc get route oauth-openshift
```

2. Check the service endpoint:

```
$ oc get svc oauth-openshift
```

NAME	TYPE	CLUSTER-IP	EXTERNAL-IP	PORT(S)	AGE
oauth-openshift	ClusterIP	172.30.19.162	<none>	443/TCP	59m

3. Attempt to reach the service from a control plane (master) node:

```
[core@master0 ~]$ curl -k https://172.30.19.162
```

```
{
  "kind": "Status",
  "apiVersion": "v1",
  "metadata": {
  },
  "status": "Failure",
  "message": "forbidden: User \"system:anonymous\" cannot get path \"^\"",
  "reason": "Forbidden",
  "details": {
  },
  "code": 403
}
```

4. Identify the **authentication-operator** errors from the **provisioner** node:

```
$ oc logs deployment/authentication-operator -n openshift-authentication-operator
```

```
Event(v1.ObjectReference{Kind:"Deployment", Namespace:"openshift-authentication-operator", Name:"authentication-operator", UID:"225c5bd5-b368-439b-9155-5fd3c0459d98", APIVersion:"apps/v1", ResourceVersion:"", FieldPath:""}): type: 'Normal' reason: 'OperatorStatusChanged' Status for clusteroperator/authentication changed: Degraded message changed from "IngressStateEndpointsDegraded: All 2 endpoints for oauth-server are reporting"
```

Solution

1. Ensure that the cluster name for every deployment is unique, ensuring no conflict.
2. Turn off all the rogue nodes which are not part of the cluster deployment that are using the same cluster name. Otherwise, the authentication pod of the OpenShift Container Platform cluster might never start successfully.

10.6.8.5. Failed Ignition during Firstboot

During the Firstboot, the Ignition configuration may fail.

Procedure

1. Connect to the node where the Ignition configuration failed:

```
Failed Units: 1  
machine-config-daemon-firstboot.service
```

2. Restart the **machine-config-daemon-firstboot** service:

```
[core@worker-X ~]$ sudo systemctl restart machine-config-daemon-firstboot.service
```

10.6.8.6. NTP out of sync

The deployment of OpenShift Container Platform clusters depends on NTP synchronized clocks among the cluster nodes. Without synchronized clocks, the deployment may fail due to clock drift if the time difference is greater than two seconds.

Procedure

1. Check for differences in the **AGE** of the cluster nodes. For example:

```
$ oc get nodes
```

NAME	STATUS	ROLES	AGE	VERSION
master-0.cloud.example.com	Ready	master	145m	v1.22.1
master-1.cloud.example.com	Ready	master	135m	v1.22.1
master-2.cloud.example.com	Ready	master	145m	v1.22.1
worker-2.cloud.example.com	Ready	worker	100m	v1.22.1

2. Check for inconsistent timing delays due to clock drift. For example:

```
$ oc get bmh -n openshift-machine-api
```

```
master-1 error registering master-1 ipmi://<out-of-band-ip>
```

```
$ sudo timedatectl
```

```
Local time: Tue 2020-03-10 18:20:02 UTC  
Universal time: Tue 2020-03-10 18:20:02 UTC  
RTC time: Tue 2020-03-10 18:36:53
```

Time zone: UTC (UTC, +0000)
 System clock synchronized: no
 NTP service: active
 RTC in local TZ: no

Addressing clock drift in existing clusters

1. Create a Butane config file including the contents of the **chrony.conf** file to be delivered to the nodes. In the following example, create **99-master-chrony.bu** to add the file to the control plane nodes. You can modify the file for worker nodes or repeat this procedure for the worker role.

NOTE

See "Creating machine configs with Butane" for information about Butane.

```
variant: openshift
version: 4.9.0
metadata:
  name: 99-master-chrony
  labels:
    machineconfiguration.openshift.io/role: master
storage:
files:
  - path: /etc/chrony.conf
    mode: 0644
    overwrite: true
contents:
  inline: |
    server <NTP-server> iburst ①
    stratumweight 0
    driftfile /var/lib/chrony/drift
    rtcsync
    makestep 10 3
    bindcmdaddress 127.0.0.1
    bindcmdaddress ::1
    keyfile /etc/chrony.keys
    commandkey 1
    generatecommandkey
    noclientlog
    logchange 0.5
    logdir /var/log/chrony
```

- 1 Replace <NTP-server> with the IP address of the NTP server.

2. Use Butane to generate a **MachineConfig** object file, **99-master-chrony.yaml**, containing the configuration to be delivered to the nodes:

```
$ butane 99-master-chrony.bu -o 99-master-chrony.yaml
```

3. Apply the **MachineConfig** object file:

```
$ oc apply -f 99-master-chrony.yaml
```

4. Ensure the **System clock synchronized** value is **yes**:

```
$ sudo timedatectl
```

```
Local time: Tue 2020-03-10 19:10:02 UTC
Universal time: Tue 2020-03-10 19:10:02 UTC
RTC time: Tue 2020-03-10 19:36:53
Time zone: UTC (UTC, +0000)
System clock synchronized: yes
NTP service: active
RTC in local TZ: no
```

To setup clock synchronization prior to deployment, generate the manifest files and add this file to the **openshift** directory. For example:

```
$ cp chrony-masters.yaml ~/clusterconfigs/openshift/99_masters-chrony-configuration.yaml
```

Then, continue to create the cluster.

10.6.9. Reviewing the installation

After installation, ensure the installer deployed the nodes and pods successfully.

Procedure

1. When the OpenShift Container Platform cluster nodes are installed appropriately, the following **Ready** state is seen within the **STATUS** column:

```
$ oc get nodes
```

NAME	STATUS	ROLES	AGE	VERSION
master-0.example.com	Ready	master,worker	4h	v1.22.1
master-1.example.com	Ready	master,worker	4h	v1.22.1
master-2.example.com	Ready	master,worker	4h	v1.22.1

2. Confirm the installer deployed all pods successfully. The following command removes any pods that are still running or have completed as part of the output.

```
$ oc get pods --all-namespaces | grep -iv running | grep -iv complete
```

CHAPTER 11. DEPLOYING INSTALLER-PROVISIONED CLUSTERS ON IBM CLOUD

11.1. PREREQUISITES

You can use installer-provisioned installation to install OpenShift Container Platform on IBM Cloud® nodes. This document describes the prerequisites and procedures when installing OpenShift Container Platform on IBM Cloud nodes.

IMPORTANT

Red Hat supports IPMI and PXE on the **provisioning** network only. Red Hat has not tested Red Fish, virtual media, or other complementary technologies such as Secure Boot on IBM Cloud deployments. The **provisioning** network is required.

Installer-provisioned installation of OpenShift Container Platform requires:

- One provisioner node with Red Hat Enterprise Linux CoreOS (RHCOS) 8.x installed
- Three control plane nodes
- One routable network
- One network for provisioning nodes

Before starting an installer-provisioned installation of OpenShift Container Platform on IBM Cloud, address the following prerequisites and requirements.

11.1.1. Setting up IBM Cloud infrastructure

To deploy an OpenShift Container Platform cluster on IBM Cloud®, you must first provision the IBM Cloud nodes.

IMPORTANT

Red Hat supports IPMI and PXE on the **provisioning** network only. Red Hat has not tested Red Fish, virtual media, or other complementary technologies such as Secure Boot on IBM Cloud deployments. The **provisioning** network is required.

You can customize IBM Cloud nodes using the IBM Cloud API. When creating IBM Cloud nodes, you must consider the following requirements.

Use one data center per cluster

All nodes in the OpenShift Container Platform cluster must run in the same IBM Cloud data center.

Create public and private VLANs

Create all nodes with a single public VLAN and a single private VLAN.

Ensure subnets have sufficient IP addresses

IBM Cloud public VLAN subnets use a /28 prefix by default, which provides 16 IP addresses. That is sufficient for a cluster consisting of three control plane nodes, four worker nodes, and two IP addresses for the API VIP and Ingress VIP on the **baremetal** network. For larger clusters, you might need a smaller prefix.

IBM Cloud private VLAN subnets use a **/26** prefix by default, which provides 64 IP addresses. IBM Cloud will use private network IP addresses to access the Baseboard Management Controller (BMC) of each node. OpenShift Container Platform creates an additional subnet for the **provisioning** network. Network traffic for the **provisioning** network subnet routes through the private VLAN. For larger clusters, you might need a smaller prefix.

Table 11.1. IP addresses per prefix

IP addresses	Prefix
32	/27
64	/26
128	/25
256	/24

Configuring NICs

OpenShift Container Platform deploys with two networks:

- **provisioning**: The **provisioning** network is a non-routable network used for provisioning the underlying operating system on each node that is a part of the OpenShift Container Platform cluster.
- **baremetal**: The **baremetal** network is a routable network. You can use any NIC order to interface with the **baremetal** network, provided it is not the NIC specified in the **provisioningNetworkInterface** configuration setting or the NIC associated to a node's **bootMACAddress** configuration setting for the **provisioning** network.

While the cluster nodes can contain more than two NICs, the installation process only focuses on the first two NICs. For example:

NIC	Network	VLAN
NIC1	provisioning	<provisioning_vlan>
NIC2	baremetal	<baremetal_vlan>

In the previous example, NIC1 on all control plane and worker nodes connects to the non-routable network (**provisioning**) that is only used for the installation of the OpenShift Container Platform cluster. NIC2 on all control plane and worker nodes connects to the routable **baremetal** network.

PXE	Boot order
NIC1 PXE-enabled provisioning network	1
NIC2 baremetal network.	2

NOTE

Ensure PXE is enabled on the NIC used for the **provisioning** network and is disabled on all other NICs.

Configuring canonical names

Clients access the OpenShift Container Platform cluster nodes over the **baremetal** network. Configure IBM Cloud subdomains or subzones where the canonical name extension is the cluster name.

<cluster_name>.<domain>

For example:

test-cluster.example.com

Creating DNS entries

You must create DNS **A** record entries resolving to unused IP addresses on the public subnet for the following:

Usage	Host Name	IP
API	api.<cluster_name>.<domain>	<ip>
Ingress LB (apps)	*.apps.<cluster_name>.<domain>	<ip>

Control plane and worker nodes already have DNS entries after provisioning.

The following table provides an example of fully qualified domain names. The API and Nameserver addresses begin with canonical name extensions. The host names of the control plane and worker nodes are examples, so you can use any host naming convention you prefer.

Usage	Host Name	IP
API	api.<cluster_name>.<domain>	<ip>
Ingress LB (apps)	*.apps.<cluster_name>.<domain>	<ip>
Provisioner node	provisioner.<cluster_name>.<domain>	<ip>
Master-0	openshift-master-0.<cluster_name>.<domain>	<ip>
Master-1	openshift-master-1.<cluster_name>.<domain>	<ip>
Master-2	openshift-master-2.<cluster_name>.<domain>	<ip>

Usage	Host Name	IP
Worker-0	openshift-worker-0. <cluster_name>.<domain>	<ip>
Worker-1	openshift-worker-1. <cluster_name>.<domain>	<ip>
Worker-n	openshift-worker-n. <cluster_name>.<domain>	<ip>

OpenShift Container Platform includes functionality that uses cluster membership information to generate **A** records. This resolves the node names to their IP addresses. After the nodes are registered with the API, the cluster can disperse node information without using CoreDNS-mDNS. This eliminates the network traffic associated with multicast DNS.

IMPORTANT

After provisioning the IBM Cloud nodes, you must create a DNS entry for the **api**. **<cluster_name>.<domain>** domain name on the external DNS because removing CoreDNS causes the local entry to disappear. Failure to create a DNS record for the **api**. **<cluster_name>.<domain>** domain name in the external DNS server prevents worker nodes from joining the cluster.

Network Time Protocol (NTP)

Each OpenShift Container Platform node in the cluster must have access to an NTP server. OpenShift Container Platform nodes use NTP to synchronize their clocks. For example, cluster nodes use SSL certificates that require validation, which might fail if the date and time between the nodes are not in sync.

IMPORTANT

Define a consistent clock date and time format in each cluster node's BIOS settings, or installation might fail.

Configure a DHCP server

IBM Cloud does not run DHCP on the public or private VLANs. After provisioning IBM Cloud nodes, you must set up a DHCP server for the public VLAN, which corresponds to OpenShift Container Platform's **baremetal** network.

NOTE

The IP addresses allocated to each node do not need to match the IP addresses allocated by the IBM Cloud provisioning system.

See the "Configuring the public subnet" section for details.

Ensure BMC access privileges

The "Remote management" page for each node on the dashboard contains the node's intelligent platform management interface (IPMI) credentials. The default IPMI privileges prevent the user from

making certain boot target changes. You must change the privilege level to **OPERATOR** so that Ironic can make those changes.

In the **install-config.yaml** file, add the **privilegelevel** parameter to the URLs used to configure each BMC. See the "Configuring the install-config.yaml file" section for additional details. For example:

```
ipmi://<IP>:<port>?privilegelevel=OPERATOR
```

Alternatively, contact IBM Cloud support and request that they increase the IPMI privileges to **ADMINISTRATOR** for each node.

Create bare metal servers

Create bare metal servers in the [IBM Cloud dashboard](#) by navigating to **Create resource → Bare Metal Server**.

Alternatively, you can create bare metal servers with the **ibmcloud** CLI utility. For example:

```
$ ibmcloud sl hardware create --hostname <SERVERNAME> \
    --domain <DOMAIN> \
    --size <SIZE> \
    --os <OS-TYPE> \
    --datacenter <DC-NAME> \
    --port-speed <SPEED> \
    --billing <BILLING>
```

See [Installing the stand-alone IBM Cloud CLI](#) for details on installing the IBM Cloud CLI.

NOTE

IBM Cloud servers might take 3–5 hours to become available.

11.2. SETTING UP THE ENVIRONMENT FOR AN OPENSHIFT CONTAINER PLATFORM INSTALLATION

11.2.1. Preparing the provisioner node for OpenShift Container Platform installation on IBM Cloud

Perform the following steps to prepare the provisioner node.

Procedure

1. Log in to the provisioner node via **ssh**.
2. Create a non-root user (**kni**) and provide that user with **sudo** privileges:

```
# useradd kni
# passwd kni
# echo "kni ALL=(root) NOPASSWD:ALL" | tee -a /etc/sudoers.d/kni
# chmod 0440 /etc/sudoers.d/kni
```

3. Create an **ssh** key for the new user:

```
# su - kni -c "ssh-keygen -f /home/kni/.ssh/id_rsa -N ""
```

4. Log in as the new user on the provisioner node:

```
# su - kni
```

5. Use Red Hat Subscription Manager to register the provisioner node:

```
$ sudo subscription-manager register --username=<user> --password=<pass> --auto-attach
```

```
$ sudo subscription-manager repos --enable=rhel-8-for-x86_64-appstream-rpms \
--enable=rhel-8-for-x86_64-baseos-rpms
```

NOTE

For more information about Red Hat Subscription Manager, see [Using and Configuring Red Hat Subscription Manager](#).

6. Install the following packages:

```
$ sudo dnf install -y libvirt qemu-kvm mkisofs python3-devel jq ipmitool
```

7. Modify the user to add the **libvirt** group to the newly created user:

```
$ sudo usermod --append --groups libvirt kni
```

8. Start **firewalld**:

```
$ sudo systemctl start firewalld
```

9. Enable **firewalld**:

```
$ sudo systemctl enable firewalld
```

10. Start the **http** service:

```
$ sudo firewall-cmd --zone=public --add-service=http --permanent
```

```
$ sudo firewall-cmd --reload
```

11. Start and enable the **libvirtd** service:

```
$ sudo systemctl enable libvirtd --now
```

12. Set the ID of the provisioner node:

```
$ PRVN_HOST_ID=<ID>
```

You can view the ID with the following **ibmcloud** command:

```
$ ibmcloud sl hardware list
```

13. Set the ID of the public subnet:

```
$ PUBLICSUBNETID=<ID>
```

You can view the ID with the following **ibmcloud** command:

```
$ ibmcloud sl subnet list
```

14. Set the ID of the private subnet:

```
$ PRIVSUBNETID=<ID>
```

You can view the ID with the following **ibmcloud** command:

```
$ ibmcloud sl subnet list
```

15. Set the provisioner node public IP address:

```
$ PRVN_PUB_IP=$(ibmcloud sl hardware detail $PRVN_HOST_ID --output JSON | jq .primaryIpAddress -r)
```

16. Set the CIDR for the public network:

```
$ PUBLICCIDR=$(ibmcloud sl subnet detail $PUBLICSUBNETID --output JSON | jq .cidr)
```

17. Set the IP address and CIDR for the public network:

```
$ PUB_IP_CIDR=$PRVN_PUB_IP/$PUBLICCIDR
```

18. Set the gateway for the public network:

```
$ PUB_GATEWAY=$(ibmcloud sl subnet detail $PUBLICSUBNETID --output JSON | jq .gateway -r)
```

19. Set the private IP address of the provisioner node:

```
$ PRVN_PRIV_IP=$(ibmcloud sl hardware detail $PRVN_HOST_ID --output JSON | jq .primaryBackendIpAddress -r)
```

20. Set the CIDR for the private network:

```
$ PRIVCIDR=$(ibmcloud sl subnet detail $PRIVSUBNETID --output JSON | jq .cidr)
```

21. Set the IP address and CIDR for the private network:

```
$ PRIV_IP_CIDR=$PRVN_PRIV_IP/$PRIVCIDR
```

22. Set the gateway for the private network:

```
$ PRIV_GATEWAY=$(ibmcloud sl subnet detail $PRIVSUBNETID --output JSON | jq .gateway -r)
```

23. Set up the bridges for the **baremetal** and **provisioning** networks:

```
$ sudo nohup bash -c "
    nmcli --get-values UUID con show | xargs -n 1 nmcli con delete
    nmcli connection add ifname provisioning type bridge con-name provisioning
    nmcli con add type bridge-slave ifname eth1 master provisioning
    nmcli connection add ifname baremetal type bridge con-name baremetal
    nmcli con add type bridge-slave ifname eth2 master baremetal
    nmcli connection modify baremetal ipv4.addresses $PUB_IP_CIDR ipv4.method manual
    ipv4.gateway $PUB_GATEWAY
    nmcli connection modify provisioning ipv4.addresses 172.22.0.1/24,$PRIV_IP_CIDR
    ipv4.method manual
    nmcli connection modify provisioning +ipv4.routes \"10.0.0.0/8 $PRIV_GATEWAY\"
    nmcli con down baremetal
    nmcli con up baremetal
    nmcli con down provisioning
    nmcli con up provisioning
    init 6
"
```

NOTE

For **eth1** and **eth2**, substitute the appropriate interface name, as needed.

24. If required, SSH back into the **provisioner** node:

```
# ssh kni@provisioner.<cluster-name>.<domain>
```

25. Verify the connection bridges have been properly created:

```
$ sudo nmcli con show
```

Example output

NAME	UUID	TYPE	DEVICE
baremetal	4d5133a5-8351-4bb9-bfd4-3af264801530	bridge	baremetal
provisioning	43942805-017f-4d7d-a2c2-7cb3324482ed	bridge	provisioning
virbr0	d9bca40f-eee1-410b-8879-a2d4bb0465e7	bridge	virbr0
bridge-slave-eth1	76a8ed50-c7e5-4999-b4f6-6d9014dd0812	ethernet	eth1
bridge-slave-eth2	f31c3353-54b7-48de-893a-02d2b34c4736	ethernet	eth2

26. Create a **pull-secret.txt** file:

```
$ vim pull-secret.txt
```

In a web browser, navigate to [Install on Bare Metal with user-provisioned infrastructure](#). In step 1, click **Download pull secret**. Paste the contents into the **pull-secret.txt** file and save the contents in the **kni** user's home directory.

11.2.2. Configuring the public subnet

All of the OpenShift Container Platform cluster nodes must be on the public subnet. IBM Cloud® does not provide a DHCP server on the subnet. Set it up separately on the provisioner node.

You must reset the BASH variables defined when preparing the provisioner node. Rebooting the provisioner node after preparing it will delete the BASH variables previously set.

Procedure

1. Install **dnsmasq**:

```
$ sudo dnf install dnsmasq
```

2. Open the **dnsmasq** configuration file:

```
$ sudo vi /etc/dnsmasq.conf
```

3. Add the following configuration to the **dnsmasq** configuration file:

```
interface=baremetal
except-interface=lo
bind-dynamic
log-dhcp

dhcp-range=<ip_addr>,<ip_addr>,<pub_cidr> ①
dhcp-option=baremetal,121,0.0.0.0/0,<pub_gateway>,<prvn_priv_ip>,<prvn_pub_ip> ②

dhcp-hostsfile=/var/lib/dnsmasq/dnsmasq.hostsfile
```

- 1 Set the DHCP range. Replace both instances of **<ip_addr>** with one unused IP address from the public subnet so that the **dhcp-range** for the **baremetal** network begins and ends with the same the IP address. Replace **<pub_cidr>** with the CIDR of the public subnet.
- 2 Set the DHCP option. Replace **<pub_gateway>** with the IP address of the gateway for the **baremetal** network. Replace **<prvn_priv_ip>** with the IP address of the provisioner node's private IP address on the **provisioning** network. Replace **<prvn_pub_ip>** with the IP address of the provisioner node's public IP address on the **baremetal** network.

To retrieve the value for **<pub_cidr>**, execute:

```
$ ibmcloud sl subnet detail <publicsubnetid> --output JSON | jq .cidr
```

Replace **<publicsubnetid>** with the ID of the public subnet.

To retrieve the value for **<pub_gateway>**, execute:

```
$ ibmcloud sl subnet detail <publicsubnetid> --output JSON | jq .gateway -r
```

Replace **<publicsubnetid>** with the ID of the public subnet.

To retrieve the value for **<prvn_priv_ip>**, execute:

```
$ ibmcloud sl hardware detail <id> --output JSON | \
    jq .primaryBackendIpAddress -r
```

Replace **<id>** with the ID of the provisioner node.

To retrieve the value for **<prvn_pub_ip>**, execute:

```
$ ibmcloud sl hardware detail <id> --output JSON | jq .primaryIpAddress -r
```

Replace **<id>** with the ID of the provisioner node.

- Obtain the list of hardware for the cluster:

```
$ ibmcloud sl hardware list
```

- Obtain the MAC addresses and IP addresses for each node:

```
$ ibmcloud sl hardware detail <id> --output JSON | \
    jq '.networkComponents[] | \
        "\(.primaryIpAddress) \(.macAddress)"' | grep -v null
```

Replace **<id>** with the ID of the node.

Example output

```
"10.196.130.144 00:e0:ed:6a:ca:b4"
"141.125.65.215 00:e0:ed:6a:ca:b5"
```

Make a note of the MAC address and IP address of the public network. Make a separate note of the MAC address of the private network, which you will use later in the **install-config.yaml** file. Repeat this procedure for each node until you have all the public MAC and IP addresses for the public **baremetal** network, and the MAC addresses of the private **provisioning** network.

- Add the MAC and IP address pair of the public **baremetal** network for each node into the **dnsmasq.hostsfile** file:

```
$ sudo vim /var/lib/dnsmasq/dnsmasq.hostsfile
```

Example input

```
00:e0:ed:6a:ca:b5,141.125.65.215,master-0
<mac>,<ip>,master-1
<mac>,<ip>,master-2
<mac>,<ip>,worker-0
<mac>,<ip>,worker-1
...
...
```

Replace **<mac>,<ip>** with the public MAC address and public IP address of the corresponding node name.

- Start **dnsmasq**:

```
$ sudo systemctl start dnsmasq
```

8. Enable **dnsmasq** so that it starts when booting the node:

```
$ sudo systemctl enable dnsmasq
```

9. Verify **dnsmasq** is running:

```
$ sudo systemctl status dnsmasq
```

Example output

```
● dnsmasq.service - DNS caching server.
  Loaded: loaded (/usr/lib/systemd/system/dnsmasq.service; enabled; vendor preset: disabled)
  Active: active (running) since Tue 2021-10-05 05:04:14 CDT; 49s ago
    Main PID: 3101 (dnsmasq)
      Tasks: 1 (limit: 204038)
     Memory: 732.0K
        CGrou: /system.slice/dnsmasq.service
             └─3101 /usr/sbin/dnsmasq -k
```

10. Open ports **53** and **67** with UDP protocol:

```
$ sudo firewall-cmd --add-port 53/udp --permanent
```

```
$ sudo firewall-cmd --add-port 67/udp --permanent
```

11. Add **provisioning** to the external zone with masquerade:

```
$ sudo firewall-cmd --change-zone=provisioning --zone=external --permanent
```

This step ensures network address translation for IPMI calls to the management subnet.

12. Reload the **firewalld** configuration:

```
$ sudo firewall-cmd --reload
```

11.2.3. Retrieving the OpenShift Container Platform installer

Use the **latest-4.x** version of the installer to deploy the latest generally available version of OpenShift Container Platform:

```
$ export VERSION=latest-4.9
export RELEASE_IMAGE=$(curl -s https://mirror.openshift.com/pub/openshift-v4/clients/ocp/$VERSION/release.txt | grep 'Pull From: quay.io' | awk -F ' ' '{print $3}')
```

11.2.4. Extracting the OpenShift Container Platform installer

After retrieving the installer, the next step is to extract it.

Procedure

1. Set the environment variables:

-

```
$ export cmd=openshift-baremetal-install
$ export pullsecret_file=~/pull-secret.txt
$ export extract_dir=$(pwd)
```

2. Get the **oc** binary:

```
$ curl -s https://mirror.openshift.com/pub/openshift-v4/clients/ocp/$VERSION/openshift-client-linux.tar.gz | tar zxvf - oc
```

3. Extract the installer:

```
$ sudo cp oc /usr/local/bin
$ oc adm release extract --registry-config "${pullsecret_file}" --command=$cmd --to
"${extract_dir}" ${RELEASE_IMAGE}
$ sudo cp openshift-baremetal-install /usr/local/bin
```

11.2.5. Configuring the `install-config.yaml` file

The **install-config.yaml** file requires some additional details. Most of the information is teaching the installer and the resulting cluster enough about the available IBM Cloud® hardware so that it is able to fully manage it. The material difference between installing on bare metal and installing on IBM Cloud is that you must explicitly set the privilege level for IPMI in the BMC section of the **install-config.yaml** file.

Procedure

1. Configure **install-config.yaml**. Change the appropriate variables to match the environment, including **pullSecret** and **sshKey**.

```
apiVersion: v1
baseDomain: <domain>
metadata:
  name: <cluster_name>
networking:
  machineCIDR: <public_cidr>
  networkType: OVNKubernetes
compute:
- name: worker
  replicas: 2
controlPlane:
  name: master
  replicas: 3
  platform:
    baremetal: {}
platform:
  baremetal:
    apiVIP: <api_ip>
    ingressVIP: <wildcard_ip>
    provisioningNetworkInterface: <NIC1>
    provisioningNetworkCIDR: <CIDR>
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: ipmi://10.196.130.145?privilegelevel=OPERATOR ①
```

```

username: root
password: <password>
bootMACAddress: 00:e0:ed:6a:ca:b4 2
rootDeviceHints:
  deviceName: "/dev/sda"
- name: openshift-worker-0
role: worker
bmc:
  address: ipmi://<out-of-band-ip>?privilegelevel=OPERATOR 3
  username: <user>
  password: <password>
bootMACAddress: <NIC1_mac_address> 4
rootDeviceHints:
  deviceName: "/dev/sda"
pullSecret: '<pull_secret>'
sshKey: '<ssh_pub_key>'
```

1 3 The **bmc.address** provides a **privilegelevel** configuration setting with the value set to **OPERATOR**. This is required for IBM Cloud.

2 4 Add the MAC address of the private **provisioning** network NIC for the corresponding node.

NOTE

You can use the **ibmcloud** command-line utility to retrieve the password.

```
$ ibmcloud sl hardware detail <id> --output JSON | \
jq """.networkManagementIpAddress)
(.remoteManagementAccounts[0].password)""
```

Replace **<id>** with the ID of the node.

2. Create a directory to store the cluster configuration:

```
$ mkdir ~/clusterconfigs
```

3. Copy the **install-config.yaml** file into the directory:

```
$ cp install-config.yaml ~/clusterconfig
```

4. Ensure all bare metal nodes are powered off prior to installing the OpenShift Container Platform cluster:

```
$ ipmitool -I lanplus -U <user> -P <password> -H <management_server_ip> power off
```

5. Remove old bootstrap resources if any are left over from a previous deployment attempt:

```
for i in $(sudo virsh list | tail -n +3 | grep bootstrap | awk {'print $2'});
do
  sudo virsh destroy $i;
  sudo virsh undefine $i;
```

```

    sudo virsh vol-delete $i --pool $i;
    sudo virsh vol-delete $i.ign --pool $i;
    sudo virsh pool-destroy $i;
    sudo virsh pool-undefine $i;
done

```

11.2.6. Additional install-config parameters

See the following tables for the required parameters, the **hosts** parameter, and the **bmc** parameter for the **install-config.yaml** file.

Table 11.2. Required parameters

Parameters	Default	Description
baseDomain		The domain name for the cluster. For example, example.com .
bootMode	UEFI	The boot mode for a node. Options are legacy , UEFI , and UEFISecureBoot . If bootMode is not set, Ironic sets it while inspecting the node.
sshKey		The sshKey configuration setting contains the key in the ~/.ssh/id_rsa.pub file required to access the control plane nodes and worker nodes. Typically, this key is from the provisioner node.
pullSecret		The pullSecret configuration setting contains a copy of the pull secret downloaded from the Install OpenShift on Bare Metal page when preparing the provisioner node.
metadata: name:		The name to be given to the OpenShift Container Platform cluster. For example, openshift .
networking: machineCIDR:		The public CIDR (Classless Inter-Domain Routing) of the external network. For example, 10.0.0.0/24 .

Parameters	Default	Description
<pre data-bbox="198 258 409 325">compute: - name: worker</pre>		The OpenShift Container Platform cluster requires a name be provided for worker (or compute) nodes even if there are zero nodes.
<pre data-bbox="198 482 361 550">compute: replicas: 2</pre>		Replicas sets the number of worker (or compute) nodes in the OpenShift Container Platform cluster.
<pre data-bbox="198 685 409 752">controlPlane: name: master</pre>		The OpenShift Container Platform cluster requires a name for control plane (master) nodes.
<pre data-bbox="198 864 361 932">controlPlane: replicas: 3</pre>		Replicas sets the number of control plane (master) nodes included as part of the OpenShift Container Platform cluster.
provisioningNetworkInterface		The name of the network interface on nodes connected to the provisioning network. For OpenShift Container Platform 4.9 and later releases, use the bootMACAddress configuration setting to enable Ironic to identify the IP address of the NIC instead of using the provisioningNetworkInterface configuration setting to identify the name of the NIC.
defaultMachinePlatform		The default configuration used for machine pools without a platform configuration.
apiVIP	<pre data-bbox="595 1628 991 1740">api. <clusternode.clusterdomain ></pre>	<p>The VIP to use for internal API communication.</p> <p>This setting must either be provided or pre-configured in the DNS so that the default name resolves correctly.</p>

Parameters	Default	Description
disableCertificateVerification	False	redfish and redfish-virtualmedia need this parameter to manage BMC addresses. The value should be True when using a self-signed certificate for BMC addresses.
ingressVIP	test.apps.<clusternode.clusterdomain>	The VIP to use for ingress traffic.

Table 11.3. Optional Parameters

Parameters	Default	Description
provisioningDHCPRange	172.22.0.10,172.22.0.100	Defines the IP range for nodes on the provisioning network.
provisioningNetworkCIDR	172.22.0.0/24	The CIDR for the network to use for provisioning. This option is required when not using the default address range on the provisioning network.
clusterProvisioningIP	The third IP address of the provisioningNetworkCIDR .	The IP address within the cluster where the provisioning services run. Defaults to the third IP address of the provisioning subnet. For example, 172.22.0.3 .
bootstrapProvisioningIP	The second IP address of the provisioningNetworkCIDR .	The IP address on the bootstrap VM where the provisioning services run while the installer is deploying the control plane (master) nodes. Defaults to the second IP address of the provisioning subnet. For example, 172.22.0.2 or 2620:52:0:1307::2 .
externalBridge	baremetal	The name of the baremetal bridge of the hypervisor attached to the baremetal network.
provisioningBridge	provisioning	The name of the provisioning bridge on the provisioner host attached to the provisioning network.
defaultMachinePlatform		The default configuration used for machine pools without a platform configuration.
bootstrapOSImage		A URL to override the default operating system image for the bootstrap node. The URL must contain a SHA-256 hash of the image. For example: <a href="https://mirror.openshift.com/rhcos-<version>-qemu.qcow2.gz?sha256=<uncompressed_sha256>">https://mirror.openshift.com/rhcos-<version>-qemu.qcow2.gz?sha256=&ltuncompressed_sha256> .

Parameters	Default	Description
clusterOSImage		A URL to override the default operating system for cluster nodes. The URL must include a SHA-256 hash of the image. For example, <a href="https://mirror.openshift.com/images/rhcos-<version>-openstack.qcow2.gz?sha256=<compressed_sha256>">https://mirror.openshift.com/images/rhcos-<version>-openstack.qcow2.gz?sha256=<compressed_sha256> .
provisioningNetwork		<p>The provisioningNetwork configuration setting determines whether the cluster uses the provisioning network. If it does, the configuration setting also determines if the cluster manages the network.</p> <p>Disabled: Set this parameter to Disabled to disable the requirement for a provisioning network. When set to Disabled, you must only use virtual media based provisioning, or bring up the cluster using the assisted installer. If Disabled and using power management, BMCs must be accessible from the baremetal network. If Disabled, you must provide two IP addresses on the baremetal network that are used for the provisioning services.</p> <p>Managed: Set this parameter to Managed, which is the default, to fully manage the provisioning network, including DHCP, TFTP, and so on.</p> <p>Unmanaged: Set this parameter to Unmanaged to enable the provisioning network but take care of manual configuration of DHCP. Virtual media provisioning is recommended but PXE is still available if required.</p>
httpProxy		Set this parameter to the appropriate HTTP proxy used within your environment.
httpsProxy		Set this parameter to the appropriate HTTPS proxy used within your environment.
noProxy		Set this parameter to the appropriate list of exclusions for proxy usage within your environment.

Hosts

The **hosts** parameter is a list of separate bare metal assets used to build the cluster.

Table 11.4. Hosts

Name	Default	Description
name		The name of the BareMetalHost resource to associate with the details. For example, openshift-master-0 .

Name	Default	Description
role		The role of the bare metal node. Either master or worker .
bmc		Connection details for the baseboard management controller. See the BMC addressing section for additional details.
bootMACAddress		The MAC address of the NIC that the host uses for the provisioning network. Ironic retrieves the IP address using the bootMACAddress configuration setting. Then, it binds to the host.

11.2.7. Root device hints

The **rootDeviceHints** parameter enables the installer to provision the Red Hat Enterprise Linux CoreOS (RHCOS) image to a particular device. The installer examines the devices in the order it discovers them, and compares the discovered values with the hint values. The installer uses the first discovered device that matches the hint value. The configuration can combine multiple hints, but a device must match all hints for the installer to select it.

Table 11.5. Subfields

Subfield	Description
deviceName	A string containing a Linux device name like /dev/vda . The hint must match the actual value exactly.
hctl	A string containing a SCSI bus address like 0:0:0:0 . The hint must match the actual value exactly.
model	A string containing a vendor-specific device identifier. The hint can be a substring of the actual value.
vendor	A string containing the name of the vendor or manufacturer of the device. The hint can be a substring of the actual value.
serialNumber	A string containing the device serial number. The hint must match the actual value exactly.
minSizeGigabytes	An integer representing the minimum size of the device in gigabytes.
wwn	A string containing the unique storage identifier. The hint must match the actual value exactly.

Subfield	Description
wwnWithExtension	A string containing the unique storage identifier with the vendor extension appended. The hint must match the actual value exactly.
wwnVendorExtension	A string containing the unique vendor storage identifier. The hint must match the actual value exactly.
rotational	A boolean indicating whether the device should be a rotating disk (true) or not (false).

Example usage

```
- name: master-0
role: master
bmc:
  address: ipmi://10.10.0.3:6203
  username: admin
  password: redhat
bootMACAddress: de:ad:be:ef:00:40
rootDeviceHints:
  deviceName: "/dev/sda"
```

11.2.8. Creating the OpenShift Container Platform manifests

1. Create the OpenShift Container Platform manifests.

```
$ ./openshift-baremetal-install --dir ~/clusterconfigs create manifests
```

INFO Consuming Install Config from target directory
 WARNING Making control-plane schedulable by setting MastersSchedulable to true for Scheduler cluster settings
 WARNING Discarding the OpenShift Manifest that was provided in the target directory because its dependencies are dirty and it needs to be regenerated

11.2.9. Deploying the cluster via the OpenShift Container Platform installer

Run the OpenShift Container Platform installer:

```
$ ./openshift-baremetal-install --dir ~/clusterconfigs --log-level debug create cluster
```

11.2.10. Following the installation

During the deployment process, you can check the installation's overall status by issuing the **tail** command to the **.openshift_install.log** log file in the install directory folder.

```
$ tail -f /path/to/install-dir/.openshift_install.log
```

CHAPTER 12. INSTALLING WITH Z/VM ON IBM Z AND LINUXONE

12.1. PREPARING TO INSTALL WITH Z/VM ON IBM Z AND LINUXONE

12.1.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).

12.1.2. Choosing a method to install OpenShift Container Platform with z/VM on IBM Z or LinuxONE

You can install a cluster with z/VM on IBM Z or LinuxONE infrastructure that you provision, by using one of the following methods:

- **[Installing a cluster with z/VM on IBM Z and LinuxONE](#)** You can install OpenShift Container Platform with z/VM on IBM Z or LinuxONE infrastructure that you provision.
- **[Installing a cluster with z/VM on IBM Z and LinuxONE in a restricted network](#)** You can install OpenShift Container Platform with z/VM on IBM Z or LinuxONE infrastructure that you provision in a restricted or disconnected network, by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

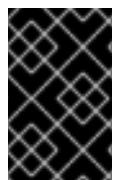

12.2. INSTALLING A CLUSTER WITH Z/VM ON IBM Z AND LINUXONE

In OpenShift Container Platform version 4.9, you can install a cluster on IBM Z or LinuxONE infrastructure that you provision.

NOTE

While this document refers only to IBM Z, all information in it also applies to LinuxONE.

IMPORTANT

Additional considerations exist for non-bare metal platforms. Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you install an OpenShift Container Platform cluster.

12.2.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).

- Before you begin the installation process, you must clean the installation directory. This ensures that the required installation files are created and updated during the installation process.
- You provisioned [persistent storage using NFS](#) for your cluster. To deploy a private image registry, your storage must provide **ReadWriteMany** access modes.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

12.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

12.2.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

12.2.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

Table 12.1. Minimum required hosts

Hosts	Description
One temporary bootstrap machine	The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

Hosts	Description
Three control plane machines	The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.
At least two compute machines, which are also known as worker machines.	The workloads requested by OpenShift Container Platform users run on the compute machines.

IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 7.9, or RHEL 8.4.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

12.2.3.2. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

Machine	Operating System	vCPU [1]	Virtual RAM	Storage	IOPS
Bootstrap	RHCOS	4	16 GB	100 GB	N/A
Control plane	RHCOS	4	16 GB	100 GB	N/A
Compute	RHCOS	2	8 GB	100 GB	N/A

- One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

12.2.3.3. Minimum IBM Z system environment

You can install OpenShift Container Platform version 4.9 on the following IBM hardware:

- IBM z15 (all models), IBM z14 (all models), IBM z13, and IBM z13s
- LinuxONE, any version

Hardware requirements

- The equivalent of 6 IFLs, which are SMT2 enabled, for each cluster.
- At least one network connection to both connect to the **LoadBalancer** service and to serve data for traffic outside the cluster.

NOTE

You can use dedicated or shared IFLs to assign sufficient compute resources. Resource sharing is one of the key strengths of IBM Z. However, you must adjust capacity correctly on each hypervisor layer and ensure sufficient resources for every OpenShift Container Platform cluster.

IMPORTANT

Since the overall performance of the cluster can be impacted, the LPARs that are used to setup the OpenShift Container Platform clusters must provide sufficient compute capacity. In this context, LPAR weight management, entitlements, and CPU shares on the hypervisor level play an important role.

Operating system requirements

- One instance of z/VM 7.1 or later

On your z/VM instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

Disk storage for the z/VM guest virtual machines

- FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV to ensure optimal performance.
- FCP attached disk storage

Storage / Main Memory

- 16 GB for OpenShift Container Platform control plane machines
- 8 GB for OpenShift Container Platform compute machines
- 16 GB for the temporary OpenShift Container Platform bootstrap machine

12.2.3.4. Preferred IBM Z system environment

Hardware requirements

- 3 LPARS that each have the equivalent of 6 IFLs, which are SMT2 enabled, for each cluster.

- Two network connections to connect to both connect to the **LoadBalancer** service and to serve data for traffic outside the cluster.
- HiperSockets, which are attached to a node either directly as a device or by bridging with one z/VM VSWITCH to be transparent to the z/VM guest. To directly connect HiperSockets to a node, you must set up a gateway to the external network via a RHEL 8 guest to bridge to the HiperSockets network.

Operating system requirements

- 2 or 3 instances of z/VM 7.1 or later for high availability

On your z/VM instances, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines, one per z/VM instance.
- At least 6 guest virtual machines for OpenShift Container Platform compute machines, distributed across the z/VM instances.
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine.
- To ensure the availability of integral components in an overcommitted environment, increase the priority of the control plane by using the CP command **SET SHARE**. Do the same for infrastructure nodes, if they exist. See [SET SHARE](#) in IBM Documentation.

IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

Disk storage for the z/VM guest virtual machines

- FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV and High Performance FICON (zHPF) to ensure optimal performance.
- FCP attached disk storage

Storage / Main Memory

- 16 GB for OpenShift Container Platform control plane machines
- 8 GB for OpenShift Container Platform compute machines
- 16 GB for the temporary OpenShift Container Platform bootstrap machine

12.2.3.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using

kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

Additional resources

- See [Bridging a HiperSockets LAN with a z/VM Virtual Switch](#) in IBM Documentation.
- See [Scaling HyperPAV alias devices on Linux guests on z/VM](#) for performance optimization.
- See [Topics in LPAR performance](#) for LPAR weight management and entitlements.
- Recommended host practices for IBM Z & LinuxONE environments

12.2.3.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

The machines are configured with static IP addresses. No DHCP server is required. Ensure that the machines have persistent IP addresses and hostnames.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

12.2.3.6.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 12.2. Ports used for all-machine to all-machine communications

Protocol	Port	Description
ICMP	N/A	Network reachability tests
TCP	1936	Metrics

Protocol	Port	Description
	9000-9999	Host level services, including the node exporter on ports 9100-9101 and the Cluster Version Operator on port 9099 .
	10250-10259	The default ports that Kubernetes reserves
	10256	openshift-sdn
UDP	4789	VXLAN and Geneve
	6081	VXLAN and Geneve
	9000-9999	Host level services, including the node exporter on ports 9100-9101 .
TCP/UDP	30000-32767	Kubernetes node port

Table 12.3. Ports used for all-machine to control plane communications

Protocol	Port	Description
TCP	6443	Kubernetes API

Table 12.4. Ports used for control plane machine to control plane machine communications

Protocol	Port	Description
TCP	2379-2380	etcd server and peer ports

NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for [Configuring chrony time service](#).

Additional resources

- [Configuring chrony time service](#)

12.2.3.7. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard

- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, **<cluster_name>** is the cluster name and **<base_domain>** is the base domain that you specify in the **install-config.yaml** file. A complete DNS record takes the form: **<component>.<cluster_name>.<base_domain>..**

Table 12.5. Required DNS records

Component	Record	Description
Kubernetes API	api.<cluster_name>.<base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.
	api-int.<cluster_name>.<base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.
Routes	*.apps.<cluster_name>.<base_domain>.	<p> IMPORTANT</p> <p>The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</p>
Bootstrap machine	bootstrap.<cluster_name>.<base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.

Component	Record	Description
Control plane machine s	<master><n>. <cluster_name>. <base_domain>.	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.
Compute machine s	<worker><n>. <cluster_name>. <base_domain>.	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

NOTE

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

TIP

You can use the **dig** command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

12.2.3.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is **ocp4** and the base domain is **example.com**.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

Example 12.1. Sample DNS zone database

```
$TTL 1W
@ IN SOA ns1.example.com. root (
    2019070700 ; serial
    3H ; refresh (3 hours)
    30M ; retry (30 minutes)
    2W ; expiry (2 weeks)
    1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
;
;
ns1.example.com. IN A 192.168.1.5
smtp.example.com. IN A 192.168.1.5
;
helper.example.com. IN A 192.168.1.5
```

```

worker1.ocp4.example.com. IN A 192.168.1.7 ⑨
;
:EOF

```

- ① Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.
- ② Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.
- ③ Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

- ④ Provides name resolution for the bootstrap machine.
- ⑤ ⑥ ⑦ Provides name resolution for the control plane machines.
- ⑧ ⑨ Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 12.2. Sample DNS zone database for reverse records

```

$TTL 1W
@ IN SOA ns1.example.com. root (
    2019070700 ; serial

```

```

3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.

;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. ①
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. ②
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. ③
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. ④
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. ⑤
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. ⑥

11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. ⑦
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. ⑧
;
:EOF

```

- ① Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
- ② Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
- ③ Provides reverse DNS resolution for the bootstrap machine.
- ④ ⑤ ⑥ Provides reverse DNS resolution for the control plane machines.
- ⑦ ⑧ Provides reverse DNS resolution for the compute machines.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

12.2.3.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer:** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
 - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
 - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**NOTE**

Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

Table 12.6. API load balancer

Port	Back-end machines (pool members)	Internal	External	Description
6443	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.	X	X	Kubernetes API server
22623	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.	X		Machine config server

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the **/readyz** endpoint to the removal of the API server instance from the pool. Within the time frame after **/readyz** returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer:** Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 12.7. Application ingress load balancer

Port	Back-end machines (pool members)	Internal	External	Description
443	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTPS traffic
80	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTP traffic

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

12.2.3.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an **/etc/haproxy/haproxy.cfg** configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 12.3. Sample API and application ingress load balancer configuration

```
global
  log    127.0.0.1 local2
  pidfile /var/run/haproxy.pid
  maxconn 4000
  daemon
defaults
  mode      http
  log       global
  option    dontlognull
  option http-server-close
  option    redispatch
  retries   3
  timeout http-request 10s
  timeout queue     1m
```

```

timeout connect      10s
timeout client       1m
timeout server       1m
timeout http-keep-alive 10s
timeout check        10s
maxconn             3000
frontend stats
  bind *:1936
  mode      http
  log       global
  maxconn  10
  stats enable
  stats hide-version
  stats refresh 30s
  stats show-node
  stats show-desc Stats for ocp4 cluster 1
  stats auth admin:ocp4
  stats uri /stats
listen api-server-6443 2
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup 3
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623 4
  bind *:22623
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup 5
  server master0 master0.ocp4.example.com:22623 check inter 1s
  server master1 master1.ocp4.example.com:22623 check inter 1s
  server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443 6
  bind *:443
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:443 check inter 1s
  server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80 7
  bind *:80
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:80 check inter 1s
  server worker1 worker1.ocp4.example.com:80 check inter 1s

```

- 1** In the example, the cluster name is **ocp4**.
- 2** Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
- 3** **5** The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.
- 4** Port **22623** handles the machine config server traffic and points to the control plane machines.
- 6** Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

- 7 Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltpu** on the HAProxy node.

NOTE

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy_connect_any=1**.

12.2.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, preparing a web server for the Ignition files, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

Prerequisites

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

Procedure

1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.

4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.
5. Setup the required DNS infrastructure for your cluster.
 - a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
 - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.
6. Validate your DNS configuration.
 - a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
 - b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.

See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.
7. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

12.2.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

- a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> 1
```

- 1 Replace **<nameserver_ip>** with the IP address of the nameserver, **<cluster_name>** with your cluster name, and **<base_domain>** with your base domain name.

Example output

```
api.ocp4.example.com. 0 IN A 192.168.1.5
```

- b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

```
api-int.ocp4.example.com. 0 IN A 192.168.1.5
```

- c. Test an example ***.apps.<cluster_name>.<base_domain>** DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

```
random.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace **random** with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

- d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

- e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.
 - a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. ①  
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. ②
```

- ① Provides the record name for the Kubernetes internal API.
- ② Provides the record name for the Kubernetes API.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

- b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

- c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

12.2.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes

through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> ①
```

1. Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> ①
```

- ① Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

12.2.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the [Infrastructure Provider](#) page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. From the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

12.2.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.9. Download and install the new version of **oc**.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.9 Linux Client** entry and save the file.
4. Unpack the archive:

```
$ tar xvzf <file>
```

5. Place the **oc** binary in a directory that is on your **PATH**.
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.9 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.

To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.9 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.

To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

12.2.9. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation_directory>**.

NOTE

You must name this configuration file **install-config.yaml**.

NOTE

For some platform types, you can alternatively run **./openshift-install create install-config --dir=<installation_directory>** to generate an **install-config.yaml** file. You can provide details about your cluster configuration at the prompts.

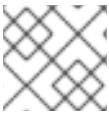

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

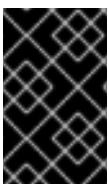

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

12.2.9.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized **install-config.yaml** installation configuration file that describes the details for your environment.

**NOTE**

After installation, you cannot modify these parameters in the **install-config.yaml** file.

**IMPORTANT**

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

12.2.9.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 12.8. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>. <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of {.metadata.name}. {.baseDomain} .	String of lowercase letters, hyphens (-), and periods (.), such as dev .

Parameter	Description	Values
platform	The configuration for the specific platform upon which to perform the installation: aws , baremetal , azure , openstack , ovirt , vsphere , or <code>{}</code> . For additional information about platform . <platform> parameters, consult the table for your specific platform that follows.	Object
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths":{ "cloud.openshift.com":{ "auth":"b3Blb=", "email":"you@example.com" }, "quay.io":{ "auth":"b3Blb=", "email":"you@example.com" } } }</pre>

12.2.9.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 12.9. Network parameters

Parameter	Description	Values
networking	The configuration for the cluster network.	<p>Object</p>  <p>NOTE</p> <p>You cannot modify parameters specified by the networking object after installation.</p>

Parameter	Description	Values
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23 . If you specify multiple IP address blocks, the blocks must not overlap.	An array of objects. For example: <pre>networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</pre>
networking.clusterNetwork.cidr	Required if you use networking.clusterNetwork . An IP address block. An IPv4 network.	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{32-23} - 2$) pod IP addresses.	A subnet prefix. The default value is 23 .
networking.serviceNetwork	The IP address block for services. The default value is 172.30.0.0/16 . The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.	An array with an IP address block in CIDR format. For example: <pre>networking: serviceNetwork: - 172.30.0.0/16</pre>
networking.machineNetwork	The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.	An array of objects. For example: <pre>networking: machineNetwork: - cidr: 10.0.0.0/16</pre>

Parameter	Description	Values
networking.machineNetwork.cidr	Required if you use networking.machineNetwork . An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24 .	<p>An IP network block in CIDR notation. For example, 10.0.0.0/16.</p>  <p>NOTE Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.</p>

12.2.9.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 12.10. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).	String

Parameter	Description	Values
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere , or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).	String

Parameter	Description	Values
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	 IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.	Mint, Passthrough, Manual , or an empty string ("").
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>NOTE</p> <p>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the <i>Cloud Credential Operator</i> entry in the <i>Red Hat Operators</i> reference content.</p>	false or true
imageContentSources	 <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.

Parameter	Description	Values
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.	Internal or External . The default value is External . Setting this field to Internal is not supported on non-cloud platforms.
sshKey	The SSH key or keys to authenticate access your cluster machines. 	One or more keys. For example: sshKey: <key1> <key2> <key3>

12.2.9.2. Sample `install-config.yaml` file for IBM Z

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```
apiVersion: v1
baseDomain: example.com ①
compute: ②
- hyperthreading: Enabled ③
  name: worker
  replicas: 0 ④
  architecture : s390x
controlPlane: ⑤
  hyperthreading: Enabled ⑥
  name: master
  replicas: 3 ⑦
  architecture : s390x
metadata:
  name: test ⑧
networking:
```

```

clusterNetwork:
- cidr: 10.128.0.0/14 9
  hostPrefix: 23 10
networkType: OpenShiftSDN
serviceNetwork: 11
- 172.30.0.0/16
platform:
  none: {} 12
  fips: false 13
pullSecret: '{"auths": ...}' 14
sshKey: 'ssh-ed25519 AAAA...' 15

```

1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2 **5** The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, **-**, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

3 **6** Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not available on your OpenShift Container Platform nodes, the **hyperthreading** parameter has no effect.

IMPORTANT

If you disable **hyperthreading**, whether on your OpenShift Container Platform nodes or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

4 You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

7 The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

- 8 The cluster name that you specified in your DNS records.
- 9 A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.
- 10 The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to **23**, then each node is assigned a /23 subnet out of the given **cidr**, which allows for 510 ($2^{(32 - 23)} - 2$) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.
- 11 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.
- 12 You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Z infrastructure.

WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as [installing a cluster on any platform](#), and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.
2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

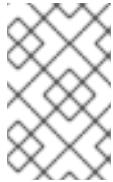

- 13 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

- 14 The pull secret that you obtained from the [Red Hat OpenShift Cluster Manager](#) site. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.
- 15 The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

12.2.9.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

- If your cluster is on AWS, you added the **ec2.<region>.amazonaws.com**, **elasticloadbalancing.<region>.amazonaws.com**, and **s3.<region>.amazonaws.com** endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
  additionalTrustBundle: | 4
    -----BEGIN CERTIFICATE-----
```

```
<MY_TRUSTED_CA_CERT>
-----END CERTIFICATE-----
```

- ...
- 1** A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpProxy** value.
 - 2** A proxy URL to use for creating HTTPS connections outside the cluster. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpsProxy** value.
 - 3** A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.
 - 4** If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace to hold the additional CA certificates. If you provide **additionalTrustBundle** and at least one proxy setting, the **Proxy** object is configured to reference the **user-ca-bundle** config map in the **trustedCA** field. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges the contents specified for the **trustedCA** parameter with the RHCOS trust bundle. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE

The installation program does not support the proxy **readinessEndpoints** field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

12.2.9.4. Configuring a three-node cluster

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing **install-config.yaml** file.

Procedure

- Ensure that the number of compute replicas is set to **0** in your **install-config.yaml** file, as shown in the following **compute** stanza:

```
compute:
- name: worker
  platform: {}
  replicas: 0
```

NOTE

You must set the value of the **replicas** parameter for the compute machines to **0** when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

NOTE

The preferred resource for control plane nodes is six vCPUs and 21 GB. For three control plane nodes this is the memory + vCPU equivalent of a minimum five-node cluster. You should back the three nodes, each installed on a 120 GB disk, with three IFLs that are SMT2 enabled. The minimum tested setup is three vCPUs and 10 GB on a 120 GB disk for each control plane node.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.
- When you create the Kubernetes manifest files in the following procedure, ensure that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file is set to **true**. This enables your application workloads to run on the control plane nodes.
- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

12.2.10. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named **cluster**. The CR specifies the fields for the **Network** API in the **operator.openshift.io** API group.

The CNO configuration inherits the following fields during cluster installation from the **Network** API in the **Network.config.openshift.io** API group and these fields cannot be changed:

clusterNetwork

IP address pools from which pod IP addresses are allocated.

serviceNetwork

IP address pool for services.

defaultNetwork.type

Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

12.2.10.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

Table 12.11. Cluster Network Operator configuration object

Field	Type	Description
metadata.name	string	The name of the CNO object. This name is always cluster .
spec.clusterNetwork	array	<p>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</p> <pre>spec: clusterNetwork: - cidr: 10.128.0.0/19 hostPrefix: 23 - cidr: 10.128.32.0/19 hostPrefix: 23</pre> <p>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</p>
spec.serviceNetwork	array	<p>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:</p> <pre>spec: serviceNetwork: - 172.30.0.0/14</pre> <p>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</p>
spec.defaultNetwork	object	Configures the Container Network Interface (CNI) cluster network provider for the cluster network.

Field	Type	Description
spec.kubeProxyConfig	object	The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

defaultNetwork object configuration

The values for the **defaultNetwork** object are defined in the following table:

Table 12.12. **defaultNetwork** object

Field	Type	Description
type	string	<p>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</p>  <p>NOTE</p> <p>OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.</p>
openshiftSDNConfig	object	This object is only valid for the OpenShift SDN cluster network provider.
ovnKubernetesConfig	object	This object is only valid for the OVN-Kubernetes cluster network provider.

Configuration for the OpenShift SDN CNI cluster network provider

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

Table 12.13. **openshiftSDNConfig** object

Field	Type	Description
mode	string	<p>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy.</p> <p>The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</p>

Field	Type	Description
mtu	integer	<p>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.</p> <p>This value cannot be changed after cluster installation.</p>
vxlanPort	integer	<p>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.</p> <p>If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.</p> <p>On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</p>

Example OpenShift SDN configuration

```
defaultNetwork:
type: OpenShiftSDN
openshiftSDNConfig:
  mode: NetworkPolicy
  mtu: 1450
  vxlanPort: 4789
```

Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

Table 12.14. `ovnKubernetesConfig` object

Field	Type	Description
mtu	integer	<p>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.</p> <p>This value cannot be changed after cluster installation.</p>
genevePort	integer	The port to use for all Geneve packets. The default value is 6081 . This value cannot be changed after cluster installation.
policyAuditConfig	object	Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.

Table 12.15. **policyAuditConfig** object

Field	Type	Description
rateLimit	integer	The maximum number of messages to generate every second per node. The default value is 20 messages per second.
maxFileSize	integer	The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.
destination	string	<p>One of the following additional audit log targets:</p> <p>libc The libc syslog() function of the journald process on the host.</p> <p>udp:<host>:<port> A syslog server. Replace <host>:<port> with the host and port of the syslog server.</p> <p>unix:<file> A Unix Domain Socket file specified by <file>.</p> <p>null Do not send the audit logs to any additional target.</p>

Field	Type	Description
syslogFacility	string	The syslog facility, such as kern , as defined by RFC5424. The default value is local0 .

Example OVN-Kubernetes configuration

```
defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
```

kubeProxyConfig object configuration

The values for the **kubeProxyConfig** object are defined in the following table:

Table 12.16. **kubeProxyConfig** object

Field	Type	Description
iptablesSyncPeriod	string	<p>The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</p> <p> NOTE</p> <p>Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary.</p>
proxyArguments.iptables-min-sync-period	array	<p>The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s, m, and h and are described in the Go time package. The default value is:</p> <p></p> <pre>kubeProxyConfig: proxyArguments: iptables-min-sync-period: - 0s</pre>

12.2.11. Creating the Kubernetes manifest and Ignition config files

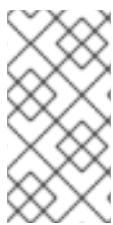

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the [client image mirror](#). The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the **install-config.yaml** installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

Example output

```
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift
```

- 1 For **<installation_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

WARNING

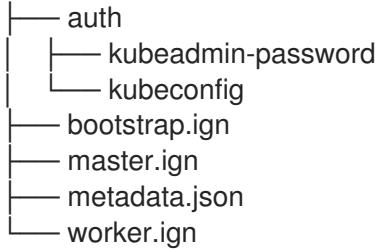

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

2. Check that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
 - a. Open the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file.
 - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
 - c. Save and exit the file.
3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory> ①
```

- ① For **<installation_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation_directory>/auth** directory:

12.2.12. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Z infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on z/VM guest virtual machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS z/VM guest virtual machines have rebooted.

Complete the following steps to create the machines.

Prerequisites

- An HTTP or HTTPS server running on your provisioning machine that is accessible to the machines you create.

Procedure

1. Log in to Linux on your provisioning machine.
2. Obtain the Red Hat Enterprise Linux CoreOS (RHCOS) kernel, initramfs, and rootfs files from the [RHCOS image mirror](#).

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described in the following procedure.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- kernel: **rhcoss-<version>-live-kernel-<architecture>**
- initramfs: **rhcoss-<version>-live-initramfs.<architecture>.img**
- rootfs: **rhcoss-<version>-live-rootfs.<architecture>.img**

NOTE

The rootfs image is the same for FCP and DASD.

3. Create parameter files. The following parameters are specific for a particular virtual machine:

- For **ip=**, specify the following seven entries:
 - i. The IP address for the machine.
 - ii. An empty string.
 - iii. The gateway.
 - iv. The netmask.
 - v. The machine host and domain name in the form **hostname.domainname**. Omit this value to let RHCOS decide.
 - vi. The network interface name. Omit this value to let RHCOS decide.
 - vii. If you use static IP addresses, specify **none**.
- For **coreos.inst.ignition_url=**, specify the Ignition file for the machine role. Use **bootstrap.ign**, **master.ign**, or **worker.ign**. Only HTTP and HTTPS protocols are supported.
- For **coreos.live.rootfs_url=**, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.
- For installations on DASD-type disks, complete the following tasks:
 - i. For **coreos.inst.install_dev=**, specify **dasda**.
 - ii. Use **rd.dasd=** to specify the DASD where RHCOS is to be installed.
 - iii. Leave all other parameters unchanged.

Example parameter file, **bootstrap-0.parm**, for the bootstrap machine:

```
rd.neednet=1 console=ttySclp0 coreos.inst.install_dev=dasda
```

```
coreos.live.rootfs_url=http://
cl1.provide.example.com:8080/assets/rhcos-live-rootfs.s390x.img
coreos.inst.ignition_url=http://cl1.provide.example.com:8080/ignition/bootstrap.ign
ip=172.18.78.2::172.18.78.1:255.255.255.0::none nameserver=172.18.78.1
rd.znet=qeth,0.0.bdf0,0.0.bdf1,0.0.bdf2,layer2=1,portno=0 zfcp.allow_lun_scan=0
cio_ignore=all,
lcondev rd.dasd=0.0.3490
```

- For installations on FCP-type disks, complete the following tasks:
 - i. Use **rd.zfcp=<adapter>,<wwpn>,<lun>** to specify the FCP disk where RHCOS is to be installed. For multipathing repeat this step for each additional path.

NOTE

When you install with multiple paths, you must enable multipathing directly after the installation, not at a later point in time, as this can cause problems.

- ii. Set the install device as: **coreos.inst.install_dev=sda**.

NOTE

If additional LUNs are configured with NPIV, FCP requires **zfcp.allow_lun_scan=0**. If you must enable **zfcp.allow_lun_scan=1** because you use a CSI driver, for example, you must configure your NPIV so that each node cannot access the boot partition of another node.

- iii. Leave all other parameters unchanged.

IMPORTANT

Additional post-installation steps are required to fully enable multipathing. For more information, see "Enabling multipathing with kernel arguments on RHCOS" in *Post-installation machine configuration tasks*.

The following is an example parameter file **worker-1.parm** for a worker node with multipathing:

```
rd.neednet=1 console=ttySCLP0 coreos.inst.install_dev=sda
coreos.live.rootfs_url=http://cl1.provide.example.com:8080/assets/rhcos-live-
rootfs.s390x.img
coreos.inst.ignition_url=http://cl1.provide.example.com:8080/ignition/worker.ign
ip=172.18.78.2::172.18.78.1:255.255.255.0::none nameserver=172.18.78.1
rd.znet=qeth,0.0.bdf0,0.0.bdf1,0.0.bdf2,layer2=1,portno=0 zfcp.allow_lun_scan=0
cio_ignore=all,
lcondev
rd.zfcp=0.0.1987,0x50050763070bc5e3,0x4008400B00000000
rd.zfcp=0.0.19C7,0x50050763070bc5e3,0x4008400B00000000
rd.zfcp=0.0.1987,0x50050763071bc5e3,0x4008400B00000000
rd.zfcp=0.0.19C7,0x50050763071bc5e3,0x4008400B00000000
```

4. Transfer the initramfs, kernel, parameter files, and RHCOS images to z/VM, for example with FTP. For details about how to transfer the files with FTP and boot from the virtual reader, see [Installing under Z/VM](#).
5. Punch the files to the virtual reader of the z/VM guest virtual machine that is to become your bootstrap node.
See [PUNCH](#) in IBM Documentation.

TIP

You can use the CP PUNCH command or, if you use Linux, the **vmur** command to transfer files between two z/VM guest virtual machines.

6. Log in to CMS on the bootstrap machine.
7. IPL the bootstrap machine from the reader:

```
$ ipl c
```

See [IPL](#) in IBM Documentation.

8. Repeat this procedure for the other machines in the cluster.

12.2.12.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the **coreos-installer** command.

12.2.12.1.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

**IMPORTANT**

When adding networking arguments manually, you must also add the **rd.neednet=1** kernel argument to bring the network up in the initramfs.

The following table provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the **ip=**, **nameserver=**, and **bond=** kernel arguments.

**NOTE**

Ordering is important when adding the kernel arguments: **ip=**, **nameserver=**, and then **bond=**.

The networking options are passed to the **dracut** tool during system boot. For more information about the networking options supported by **dracut**, see the **dracut.cmdline** manual page.

Table 12.17. Networking and bonding options for ISO installations

Description	Examples
<p>To configure an IP address, either use DHCP (ip=dhcp) or set an individual static IP address (ip=<host_ip>). If setting a static IP, you must then identify the DNS server IP address (nameserver=<dns_ip>) on each node. This example sets:</p> <ul style="list-style-type: none"> • The node's IP address to 10.10.10.2 • The gateway address to 10.10.10.254 • The netmask to 255.255.255.0 • The hostname to core0.example.com • The DNS server address to 4.4.4.41 • The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically. <p>NOTE</p>  <p>When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none nameserver=4.4.4.41</pre>
<p>Specify multiple network interfaces by specifying multiple ip= entries.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none</pre>
<p>Optional: You can configure routes to additional networks by setting an rd.route= value.</p> <p>If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.</p>	<p>To configure the default gateway:</p> <pre>ip=:10.10.10.254:::</pre> <p>To configure the route for the additional network:</p> <pre>rd.route=20.20.20.0/24:20.20.20.254:enp2s0</pre>

Description	Examples
<p>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the enp1s0 interface has a static networking configuration and DHCP is disabled for enp2s0, which is not used.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp1s0:none ip=::::core0.example.com:enp2s0:none</pre>
<p>You can combine DHCP and static IP configurations on systems with multiple network interfaces.</p>	<pre>ip=enp1s0:dhcp ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp2s0:none</pre>
<p>Optional: You can configure VLANs on individual interfaces by using the vlan= parameter.</p>	<p>To configure a VLAN on a network interface and use a static IP address:</p> <pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp2s0.100:none vlan=enp2s0.100:enp2s0</pre> <p>To configure a VLAN on a network interface and to use DHCP:</p> <pre>ip=enp2s0.100:dhcp vlan=enp2s0.100:enp2s0</pre>
<p>You can provide multiple DNS servers by adding a nameserver= entry for each server.</p>	<pre>nameserver=1.1.1.1 nameserver=8.8.8.8</pre>
<p>Optional: Bonding multiple network interfaces to a single interface is supported using the bond= option. In these two examples:</p> <ul style="list-style-type: none"> The syntax for configuring a bonded interface is: bond=name[:network_interfaces] [:options] <i>name</i> is the bonding device name (bond0), <i>network_interfaces</i> represents a comma-separated list of physical (ethernet) interfaces (em1,em2), and <i>options</i> is a comma-separated list of bonding options. Enter modinfo bonding to see available options. When you create a bonded interface using bond=, you must specify how the IP address is assigned and other information for the bonded interface. 	<p>To configure the bonded interface to use DHCP, set the bond's IP address to dhcp. For example:</p> <pre>bond=bond0:em1,em2:mode=active-backup ip=bond0:dhcp</pre> <p>To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:</p> <pre>bond=bond0:em1,em2:mode=active-backup ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:bond0:none</pre>

Description	Examples
Optional: You can configure VLANs on bonded interfaces by using the vlan= parameter.	To configure the bonded interface with a VLAN and to use DHCP: ip=bond0.100:dhcp bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0
	To configure the bonded interface with a VLAN and to use a static IP address: ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0.100:none bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0

12.2.13. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

```
$ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \ ①
--log-level=info ②
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.22.1 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

- After bootstrap process is complete, remove the bootstrap machine from the load balancer.

IMPORTANT

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

12.2.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

- Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- ① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

- Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

12.2.15. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.22.1
master-1	Ready	master	63m	v1.22.1
master-2	Ready	master	64m	v1.22.1

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-mddf5	20m	system:node:master-01.example.com	Approved,Issued
csr-z5rln	16m	system:node:worker-21.example.com	Approved,Issued

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	
Pending			
csr-c571v	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	
Pending			
...			

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	73m	v1.22.1
master-1	Ready	master	73m	v1.22.1
master-2	Ready	master	74m	v1.22.1
worker-0	Ready	worker	11m	v1.22.1
worker-1	Ready	worker	11m	v1.22.1

NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

12.2.16. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.9.0	True	False	False
baremetal	4.9.0	True	False	False
cloud-credential	4.9.0	True	False	False
cluster-autoscaler	4.9.0	True	False	False
config-operator	4.9.0	True	False	False

console	4.9.0	True	False	False	26m
csi-snapshot-controller	4.9.0	True	False	False	37m
dns	4.9.0	True	False	False	37m
etcd	4.9.0	True	False	False	36m
image-registry	4.9.0	True	False	False	31m
ingress	4.9.0	True	False	False	30m
insights	4.9.0	True	False	False	31m
kube-apiserver	4.9.0	True	False	False	26m
kube-controller-manager	4.9.0	True	False	False	36m
kube-scheduler	4.9.0	True	False	False	36m
kube-storage-version-migrator	4.9.0	True	False	False	37m
machine-api	4.9.0	True	False	False	29m
machine approver	4.9.0	True	False	False	37m
machine-config	4.9.0	True	False	False	36m
marketplace	4.9.0	True	False	False	37m
monitoring	4.9.0	True	False	False	29m

operator-lifecycle-manager-packageserver	4.9.0	True	False	False	32m
service-ca	4.9.0	True	False	False	38m
storage	4.9.0	True	False	False	37m

- Configure the Operators that are not available.

12.2.16.1. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

12.2.16.1.1. Configuring registry storage for IBM Z

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster on IBM Z.
- You have provisioned persistent storage for your cluster.

IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

NOTE

When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry
```

NOTE

If the storage type is **emptyDIR**, the replica number cannot be greater than **1**.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

Example output

```
storage:  
pvc:  
claim:
```

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

```
$ oc edit configs.imageregistry/cluster
```

Then, change the line

```
managementState: Removed
```

—
to

managementState: Managed

12.2.16.1.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage":{"emptyDir":{}}}}'
```

WARNING

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

12.2.17. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME	VERSION	AVAILABLE	PROGRESSING	DEGRADED
------	---------	-----------	-------------	----------

SINCE						
authentication	4.9.0	True	False	False	19m	
baremetal	4.9.0	True	False	False	37m	
cloud-credential	4.9.0	True	False	False	40m	
cluster-autoscaler	4.9.0	True	False	False	37m	
config-operator	4.9.0	True	False	False	38m	
console	4.9.0	True	False	False	26m	
csi-snapshot-controller		4.9.0	True	False	False	37m

insights	4.9.0	True	False	False	31m	
kube-apiserver		4.9.0	True	False	False	26m
kube-controller-manager			4.9.0	True	False	36m
kube-scheduler			4.9.0	True	False	36m
kube-storage-version-migrator			4.9.0	True	False	False
machine-api	4.9.0	True	False	False	29m	
machine approver		4.9.0	True	False	False	37m
machine-config		4.9.0	True	False	False	36m
marketplace		4.9.0	True	False	False	37m
monitoring	4.9.0	True	False	False	29m	
network	4.9.0	True	False	False	38m	
node-tuning		4.9.0	True	False	False	37m
openshift-apiserver		4.9.0	True	False	False	32m
openshift-controller-manager			4.9.0	True	False	False
openshift-samples			4.9.0	True	False	False
operator-lifecycle-manager			4.9.0	True	False	False
operator-lifecycle-manager-catalog		4.9.0	True	False	False	37m
operator-lifecycle-manager-packageserver		4.9.0	True	False	False	32m
service-ca	4.9.0	True	False	False	38m	
storage	4.9.0	True	False	False	37m	

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete ①
```

- ① For <installation_directory>, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.

- a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

Example output

NAMESPACE	NAME	READY	STATUS
RESTARTS	AGE		
openshift-apiserver-operator	openshift-apiserver-operator-85cb746d55-zqhs8	1/1	
Running 1 9m			
openshift-apiserver	apiserver-67b9g	1/1	Running 0
3m			
openshift-apiserver	apiserver-ljcmx	1/1	Running 0
1m			
openshift-apiserver	apiserver-z25h4	1/1	Running 0
2m			
openshift-authentication-operator	authentication-operator-69d5d8bf84-vh2n8	1/1	
Running 0 5m			
...			

- b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> ①
```

- ① Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.
See "Enabling multipathing with kernel arguments on RHCOS" in the *Post-installation machine configuration tasks* documentation for more information.

12.2.18. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to

the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

12.2.19. Collecting debugging information

You can gather debugging information that might help you to troubleshoot and debug certain issues with an OpenShift Container Platform installation on IBM Z.

Prerequisites

- The **oc** CLI tool installed.

Procedure

1. Log in to the cluster:

```
$ oc login -u <username>
```

2. On the node you want to gather hardware information about, start a debugging container:

```
$ oc debug node/<nodename>
```

3. Change to the **/host** file system and start **toolbox**:

```
$ chroot /host  
$ toolbox
```

4. Collect the **dbginfo** data:

```
$ dbginfo.sh
```

5. You can then retrieve the data, for example, using **scp**.

Additional resources

- [How to generate SOSREPORT within OpenShift4 nodes without SSH](#) .

12.2.20. Next steps

- [Enabling multipathing with kernel arguments on RHCOS](#) .
- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#) .

12.3. INSTALLING A CLUSTER WITH Z/VM ON IBM Z AND LINUXONE IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.9, you can install a cluster on IBM Z and LinuxONE infrastructure that you provision in a restricted network.

NOTE

While this document refers to only IBM Z, all information in it also applies to LinuxONE.

IMPORTANT

Additional considerations exist for non-bare metal platforms. Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you install an OpenShift Container Platform cluster.

12.3.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [created a mirror registry for installation in a restricted network](#) and obtained the **imageContentSources** data for your version of OpenShift Container Platform.
- Before you begin the installation process, you must move or remove any existing installation files. This ensures that the required installation files are created and updated during the installation process.

IMPORTANT

Ensure that installation steps are done from a machine with access to the installation media.

- You provisioned [persistent storage using NFS](#) for your cluster. To deploy a private image registry, your storage must provide **ReadWriteMany** access modes.
- If you use a firewall and plan to use the Telemetry service, you [configured the firewall to allow the sites](#) that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

12.3.2. About installations in restricted networks

In OpenShift Container Platform 4.9, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require internet access, so you might still require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

12.3.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

12.3.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

12.3.4. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

12.3.4.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

Table 12.18. Minimum required hosts

Hosts	Description
One temporary bootstrap machine	The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.
Three control plane machines	The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.
At least two compute machines, which are also known as worker machines.	The workloads requested by OpenShift Container Platform users run on the compute machines.

IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 7.9, or RHEL 8.4.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

12.3.4.2. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

Machine	Operating System	vCPU [1]	Virtual RAM	Storage	IOPS
Bootstrap	RHCOS	4	16 GB	100 GB	N/A
Control plane	RHCOS	4	16 GB	100 GB	N/A
Compute	RHCOS	2	8 GB	100 GB	N/A

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

12.3.4.3. Minimum IBM Z system environment

You can install OpenShift Container Platform version 4.9 on the following IBM hardware:

- IBM z15 (all models), IBM z14 (all models), IBM z13, and IBM z13s
- LinuxONE, any version

Hardware requirements

- The equivalent of 6 IFLs, which are SMT2 enabled, for each cluster.
- At least one network connection to both connect to the **LoadBalancer** service and to serve data for traffic outside the cluster.

NOTE

You can use dedicated or shared IFLs to assign sufficient compute resources. Resource sharing is one of the key strengths of IBM Z. However, you must adjust capacity correctly on each hypervisor layer and ensure sufficient resources for every OpenShift Container Platform cluster.

IMPORTANT

Since the overall performance of the cluster can be impacted, the LPARs that are used to setup the OpenShift Container Platform clusters must provide sufficient compute capacity. In this context, LPAR weight management, entitlements, and CPU shares on the hypervisor level play an important role.

Operating system requirements

- One instance of z/VM 7.1 or later

On your z/VM instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

Disk storage for the z/VM guest virtual machines

- FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV to ensure optimal performance.
- FCP attached disk storage

Storage / Main Memory

- 16 GB for OpenShift Container Platform control plane machines
- 8 GB for OpenShift Container Platform compute machines
- 16 GB for the temporary OpenShift Container Platform bootstrap machine

12.3.4.4. Preferred IBM Z system environment

Hardware requirements

- 3 LPARS that each have the equivalent of 6 IFLs, which are SMT2 enabled, for each cluster.
- Two network connections to connect to both connect to the **LoadBalancer** service and to serve data for traffic outside the cluster.
- HiperSockets, which are attached to a node either directly as a device or by bridging with one z/VM VSWITCH to be transparent to the z/VM guest. To directly connect HiperSockets to a node, you must set up a gateway to the external network via a RHEL 8 guest to bridge to the HiperSockets network.

Operating system requirements

- 2 or 3 instances of z/VM 7.1 or later for high availability

On your z/VM instances, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines, one per z/VM instance.
- At least 6 guest virtual machines for OpenShift Container Platform compute machines, distributed across the z/VM instances.
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine.
- To ensure the availability of integral components in an overcommitted environment, increase the priority of the control plane by using the CP command **SET SHARE**. Do the same for infrastructure nodes, if they exist. See **SET SHARE** in IBM Documentation.

IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

Disk storage for the z/VM guest virtual machines

- FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV and High Performance FICON (zHPF) to ensure optimal performance.
- FCP attached disk storage

Storage / Main Memory

- 16 GB for OpenShift Container Platform control plane machines
- 8 GB for OpenShift Container Platform compute machines
- 16 GB for the temporary OpenShift Container Platform bootstrap machine

12.3.4.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

Additional resources

- See [Bridging a HiperSockets LAN with a z/VM Virtual Switch](#) in IBM Documentation.
- See [Scaling HyperPAV alias devices on Linux guests on z/VM](#) for performance optimization.
- See [Topics in LPAR performance](#) for LPAR weight management and entitlements.
- [Recommended host practices for IBM Z & LinuxONE environments](#)

12.3.4.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.

NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

12.3.4.6.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

12.3.4.6.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

Table 12.19. Ports used for all-machine to all-machine communications

Protocol	Port	Description
ICMP	N/A	Network reachability tests
TCP	1936	Metrics
	9000-9999	Host level services, including the node exporter on ports 9100-9101 and the Cluster Version Operator on port 9099 .
	10250-10259	The default ports that Kubernetes reserves
	10256	openshift-sdn
UDP	4789	VXLAN and Geneve
	6081	VXLAN and Geneve
	9000-9999	Host level services, including the node exporter on ports 9100-9101 .
TCP/UDP	30000-32767	Kubernetes node port

Table 12.20. Ports used for all-machine to control plane communications

Protocol	Port	Description
TCP	6443	Kubernetes API

Table 12.21. Ports used for control plane machine to control plane machine communications

Protocol	Port	Description
TCP	2379-2380	etcd server and peer ports

NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

Additional resources

- [Configuring chrony time service](#)

12.3.4.7. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, **<cluster_name>** is the cluster name and **<base_domain>** is the base domain that you specify in the **install-config.yaml** file. A complete DNS record takes the form: **<component>.<cluster_name>.<base_domain>..**

Table 12.22. Required DNS records

Component	Record	Description
Kubernetes API	api.<cluster_name>.<base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.

Component	Record	Description
	<code>api-int.<cluster_name>. <base_domain>.</code>	<p>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</p>  <p>IMPORTANT</p> <p>The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</p>
Routes	<code>*.apps.<cluster_name>. <base_domain>.</code>	<p>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</p> <p>For example, <code>console-openshift-console.apps.<cluster_name>. <base_domain></code> is used as a wildcard route to the OpenShift Container Platform console.</p>
Bootstrap machine	<code>bootstrap.<cluster_name>. <base_domain>.</code>	<p>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</p>
Control plane machines	<code><master><n>. <cluster_name>. <base_domain>.</code>	<p>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</p>
Compute machines	<code><worker><n>. <cluster_name>. <base_domain>.</code>	<p>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</p>

NOTE

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

TIP

You can use the `dig` command to verify name and reverse name resolution. See the section on [Validating DNS resolution for user-provisioned infrastructure](#) for detailed validation steps.

12.3.4.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is **ocp4** and the base domain is **example.com**.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

Example 12.4. Sample DNS zone database

```

```

- ① Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
- ② Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

3 Provides reverse DNS resolution for the bootstrap machine.

4 5 6 Provides reverse DNS resolution for the control plane machines.

7 8 Provides reverse DNS resolution for the compute machines.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

12.3.4.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer:** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
 - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
 - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

NOTE

Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

Table 12.23. API load balancer

Port	Back-end machines (pool members)	Internal	External	Description
6443	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.	X	X	Kubernetes API server
22623	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.	X		Machine config server

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer.** Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 12.24. Application ingress load balancer

Port	Back-end machines (pool members)	Internal	External	Description
443	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTPS traffic
80	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTP traffic

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

12.3.4.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an [/etc/haproxy/haproxy.cfg](#) configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 12.6. Sample API and application ingress load balancer configuration

```

global
  log    127.0.0.1 local2
  pidfile /var/run/haproxy.pid
  maxconn 4000
  daemon
defaults
  mode      http
  log       global
  option    dontlognull
  option http-server-close
  option    redispatch
  retries   3
  timeout http-request 10s
  timeout queue     1m
  timeout connect   10s
  timeout client    1m
  timeout server    1m
  timeout http-keep-alive 10s
  timeout check     10s
  maxconn   3000
frontend stats
  bind *:1936
  mode      http
  log       global
  maxconn 10
  stats enable
  stats hide-version
  stats refresh 30s
  stats show-node
  stats show-desc Stats for ocp4 cluster ①
  stats auth admin:ocp4
  stats uri /stats
listen api-server-6443 ②
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup ③
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623 ④

```

```

bind *:22623
mode tcp
server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup 5
server master0 master0.ocp4.example.com:22623 check inter 1s
server master1 master1.ocp4.example.com:22623 check inter 1s
server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443 6
bind *:443
mode tcp
balance source
server worker0 worker0.ocp4.example.com:443 check inter 1s
server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80 7
bind *:80
mode tcp
balance source
server worker0 worker0.ocp4.example.com:80 check inter 1s
server worker1 worker1.ocp4.example.com:80 check inter 1s

```

- 1 In the example, the cluster name is **ocp4**.
- 2 Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
- 3 5 The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.
- 4 Port **22623** handles the machine config server traffic and points to the control plane machines.
- 6 Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
- 7 Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltpu** on the HAProxy node.

NOTE

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy_connect_any=1**.

12.3.5. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

Prerequisites

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
 - a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
 - b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

NOTE

If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

- c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the *Setting the cluster node hostnames through DHCP* section for details about hostname considerations.

NOTE

If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.

3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.
4. Setup the required DNS infrastructure for your cluster.
 - a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
 - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.
5. Validate your DNS configuration.
 - a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
 - b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.

See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.
6. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

12.3.6. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

- a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> 1
```

- 1 Replace **<nameserver_ip>** with the IP address of the nameserver, **<cluster_name>** with your cluster name, and **<base_domain>** with your base domain name.

Example output

```
api.ocp4.example.com. 0 IN A 192.168.1.5
```

- b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

```
api-int.ocp4.example.com. 0 IN A 192.168.1.5
```

- c. Test an example ***.apps.<cluster_name>.<base_domain>** DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

```
random.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace **random** with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

- d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

- e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.
 - a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. ①  
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. ②
```

- ① Provides the record name for the Kubernetes internal API.
- ② Provides the record name for the Kubernetes API.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

- b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

- c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

12.3.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes

through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> ①
```

1. Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> ①
```

- ① Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

12.3.8. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation_directory>**.

NOTE

You must name this configuration file **install-config.yaml**.

NOTE

For some platform types, you can alternatively run `./openshift-install create install-config --dir=<installation_directory>` to generate an **install-config.yaml** file. You can provide details about your cluster configuration at the prompts.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

12.3.8.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized **install-config.yaml** installation configuration file that describes the details for your environment.

NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

IMPORTANT

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

12.3.8.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 12.25. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>, <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}} .	String of lowercase letters, hyphens (-), and periods (.), such as dev .
platform	The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere , or {} . For additional information about platform , <platform> parameters, consult the table for your specific platform that follows.	Object

Parameter	Description	Values
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths": { "cloud.openshift.com": { "auth": "b3Blb=", "email": "you@example.com" }, "quay.io": { "auth": "b3Blb=", "email": "you@example.com" } } }</pre>

12.3.8.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 12.26. Network parameters

Parameter	Description	Values
networking	The configuration for the cluster network.	Object  NOTE You cannot modify parameters specified by the networking object after installation.
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23 . If you specify multiple IP address blocks, the blocks must not overlap.	An array of objects. For example: <pre>networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</pre>

Parameter	Description	Values
networking.clusterNetwork.cidr	Required if you use networking.clusterNetwork . An IP address block. An IPv4 network.	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{(32 - 23)} - 2$) pod IP addresses.	A subnet prefix. The default value is 23 .
networking.serviceNetwork	The IP address block for services. The default value is 172.30.0.0/16 . The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.	An array with an IP address block in CIDR format. For example: <pre>networking: serviceNetwork: - 172.30.0.0/16</pre>
networking.machineNetwork	The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.	An array of objects. For example: <pre>networking: machineNetwork: - cidr: 10.0.0.0/16</pre>
networking.machineNetwork.cidr	Required if you use networking.machineNetwork . An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24 .	An IP network block in CIDR notation. For example, 10.0.0.0/16 .

**NOTE**

Set the **networking.machineNetwork** to match the CIDR that the preferred NIC resides in.

12.3.8.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 12.27. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).	String
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	 IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .

Parameter	Description	Values
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).	String
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	 IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	<p>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</p>  <p>NOTE</p> <p>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the <i>Cloud Credential Operator</i> entry in the <i>Red Hat Operators</i> reference content.</p>	Mint, Passthrough, Manual , or an empty string ("").
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	false or true

Parameter	Description	Values
imageContentSources	Sources and repositories for the release-image content.	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.	Internal or External . The default value is External . Setting this field to Internal is not supported on non-cloud platforms.
sshKey	The SSH key or keys to authenticate access your cluster machines. 	One or more keys. For example: sshKey: <key1> <key2> <key3>

12.3.8.2. Sample `install-config.yaml` file for IBM Z

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```
apiVersion: v1
baseDomain: example.com 1
compute: 2
- hyperthreading: Enabled 3
  name: worker
replicas: 0 4
  architecture : s390x
controlPlane: 5
    hyperthreading: Enabled 6
```

- 1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.
 - 2 5 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.
 - 3 6 Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not available on your OpenShift Container Platform nodes, the **hyperthreading** parameter has no effect.

IMPORTANT

If you disable **hyperthreading**, whether on your OpenShift Container Platform nodes or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

- 4 You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

- 7 The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.
- 8 The cluster name that you specified in your DNS records.
- 9 A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.
- 10 The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to **23**, then each node is assigned a /23 subnet out of the given **cidr**, which allows for 510 ($2^{32} - 2^{23} - 2$) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.
- 11 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.
- 12 You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Z infrastructure.

WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as [installing a cluster on any platform](#), and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.
2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

13

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

14

For **<local_registry>**, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, **registry.example.com** or **registry.example.com:5000**. For **<credentials>**, specify the base64-encoded user name and password for your mirror registry.

15

The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

16

Add the **additionalTrustBundle** parameter and value. The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

17

Provide the **imageContentSources** section from the output of the command to mirror the repository.

12.3.8.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

- If your cluster is on AWS, you added the **ec2.<region>.amazonaws.com**, **elasticloadbalancing.<region>.amazonaws.com**, and **s3.<region>.amazonaws.com** endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

- 1 Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ①
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
  noProxy: example.com ③
  additionalTrustBundle: | ④
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
  ...
  ...
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpProxy** value.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpsProxy** value.

- ③ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, exclude=.example.com.
- ④ If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace to hold the additional CA certificates. If you provide **additionalTrustBundle** and at least one proxy setting, the **Proxy** object is configured to reference the **user-ca-bundle** config map in the **trustedCA** field. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges the contents specified for the **trustedCA** parameter with the RHCOS trust bundle. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE

The installation program does not support the proxy **readinessEndpoints** field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

12.3.8.4. Configuring a three-node cluster

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing **install-config.yaml** file.

Procedure

- Ensure that the number of compute replicas is set to **0** in your **install-config.yaml** file, as shown in the following **compute** stanza:

```
compute:
  - name: worker
    platform: {}
    replicas: 0
```

NOTE

You must set the value of the **replicas** parameter for the compute machines to **0** when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

NOTE

The preferred resource for control plane nodes is six vCPUs and 21 GB. For three control plane nodes this is the memory + vCPU equivalent of a minimum five-node cluster. You should back the three nodes, each installed on a 120 GB disk, with three IFLs that are SMT2 enabled. The minimum tested setup is three vCPUs and 10 GB on a 120 GB disk for each control plane node.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.
- When you create the Kubernetes manifest files in the following procedure, ensure that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file is set to **true**. This enables your application workloads to run on the control plane nodes.
- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

12.3.9. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named **cluster**. The CR specifies the fields for the **Network** API in the **operator.openshift.io** API group.

The CNO configuration inherits the following fields during cluster installation from the **Network** API in the **Network.config.openshift.io** API group and these fields cannot be changed:

clusterNetwork

IP address pools from which pod IP addresses are allocated.

serviceNetwork

IP address pool for services.

defaultNetwork.type

Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

12.3.9.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

Table 12.28. Cluster Network Operator configuration object

Field	Type	Description
metadata.name	string	The name of the CNO object. This name is always cluster .
spec.clusterNetwork	array	<p>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</p> <pre>spec: clusterNetwork: - cidr: 10.128.0.0/19 hostPrefix: 23 - cidr: 10.128.32.0/19 hostPrefix: 23</pre> <p>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</p>
spec.serviceNetwork	array	<p>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:</p> <pre>spec: serviceNetwork: - 172.30.0.0/14</pre> <p>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</p>
spec.defaultNetwork	object	Configures the Container Network Interface (CNI) cluster network provider for the cluster network.
spec.kubeProxyConfig	object	The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

defaultNetwork object configuration

The values for the **defaultNetwork** object are defined in the following table:

Table 12.29. defaultNetwork object

Field	Type	Description
type	string	<p>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</p>  <p>NOTE</p> <p>OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.</p>
openshiftSDNConfig	object	This object is only valid for the OpenShift SDN cluster network provider.
ovnKubernetesConfig	object	This object is only valid for the OVN-Kubernetes cluster network provider.

Configuration for the OpenShift SDN CNI cluster network provider

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

Table 12.30. **openshiftSDNConfig** object

Field	Type	Description
mode	string	<p>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy.</p> <p>The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</p>

Field	Type	Description
mtu	integer	<p>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.</p> <p>This value cannot be changed after cluster installation.</p>
vxlanPort	integer	<p>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.</p> <p>If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.</p> <p>On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</p>

Example OpenShift SDN configuration

```
defaultNetwork:
type: OpenShiftSDN
openshiftSDNConfig:
  mode: NetworkPolicy
  mtu: 1450
  vxlanPort: 4789
```

Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

Table 12.31. ovnKubernetesConfig object

Field	Type	Description

Field	Type	Description
mtu	integer	<p>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.</p> <p>This value cannot be changed after cluster installation.</p>
genevePort	integer	The port to use for all Geneve packets. The default value is 6081 . This value cannot be changed after cluster installation.
policyAuditConfig	object	Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.

Table 12.32. **policyAuditConfig** object

Field	Type	Description
rateLimit	integer	The maximum number of messages to generate every second per node. The default value is 20 messages per second.
maxFileSize	integer	The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.

Field	Type	Description
destination	string	<p>One of the following additional audit log targets:</p> <ul style="list-style-type: none"> libc The libc syslog() function of the journald process on the host. udp:<host>:<port> A syslog server. Replace <host>:<port> with the host and port of the syslog server. unix:<file> A Unix Domain Socket file specified by <file>. null Do not send the audit logs to any additional target.
syslogFacility	string	The syslog facility, such as kern , as defined by RFC5424. The default value is local0 .

Example OVN-Kubernetes configuration

```
defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
```

kubeProxyConfig object configuration

The values for the **kubeProxyConfig** object are defined in the following table:

Table 12.33. **kubeProxyConfig** object

Field	Type	Description
iptablesSyncPeriod	string	<p>The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</p> <div style="display: flex; align-items: center; justify-content: space-between;"> <div style="flex-grow: 1; margin-right: 20px;">  </div> <div> NOTE <p>Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary.</p> </div> </div>

Field	Type	Description
proxyArguments.iptables-min-sync-period	array	<p>The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s, m, and h and are described in the Go time package. The default value is:</p> <pre>kubeProxyConfig: proxyArguments: iptables-min-sync-period: - 0s</pre>

12.3.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the [client image mirror](#). The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the **install-config.yaml** installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

Example output

```
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift
```

- For <installation_directory>, specify the installation directory that contains the **install-config.yaml** file you created.

WARNING

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

- Check that the **mastersSchedulable** parameter in the <installation_directory>/manifests/cluster-scheduler-02-config.yml Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
 - Open the <installation_directory>/manifests/cluster-scheduler-02-config.yml file.
 - Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
 - Save and exit the file.
- To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory> ①
```

- For <installation_directory>, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the <installation_directory>/auth directory:

12.3.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Z infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on z/VM guest virtual machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS z/VM guest virtual machines have rebooted.

Complete the following steps to create the machines.

Prerequisites

- An HTTP or HTTPS server running on your provisioning machine that is accessible to the machines you create.

Procedure

1. Log in to Linux on your provisioning machine.
2. Obtain the Red Hat Enterprise Linux CoreOS (RHCOS) kernel, initramfs, and rootfs files from the [RHCOS image mirror](#).

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described in the following procedure.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- kernel: **rhcoss-<version>-live-kernel-<architecture>**
- initramfs: **rhcoss-<version>-live-initramfs.<architecture>.img**
- rootfs: **rhcoss-<version>-live-rootfs.<architecture>.img**

NOTE

The rootfs image is the same for FCP and DASD.

3. Create parameter files. The following parameters are specific for a particular virtual machine:
 - For **ip=**, specify the following seven entries:
 - i. The IP address for the machine.
 - ii. An empty string.
 - iii. The gateway.

- iv. The netmask.
- v. The machine host and domain name in the form **hostname.domainname**. Omit this value to let RHCOS decide.
- vi. The network interface name. Omit this value to let RHCOS decide.
- vii. If you use static IP addresses, specify **none**.
- For **coreos.inst.ignition_url=**, specify the Ignition file for the machine role. Use **bootstrap.ign**, **master.ign**, or **worker.ign**. Only HTTP and HTTPS protocols are supported.
- For **coreos.live.rootfs_url=**, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.
- For installations on DASD-type disks, complete the following tasks:
 - i. For **coreos.inst.install_dev=**, specify **dasda**.
 - ii. Use **rd.dasd=** to specify the DASD where RHCOS is to be installed.
 - iii. Leave all other parameters unchanged.

Example parameter file, **bootstrap-0.parm**, for the bootstrap machine:

```
rd.neednet=1 console=ttySCLP0 coreos.inst.install_dev=dasda
coreos.live.rootfs_url=http://
cl1.provide.example.com:8080/assets/rhcos-live-rootfs.s390x.img
coreos.inst.ignition_url=http://cl1.provide.example.com:8080/ignition/bootstrap.ign
ip=172.18.78.2::172.18.78.1:255.255.255.0::none nameserver=172.18.78.1
rd.znet=qeth,0.0.bdf0,0.0.bdf1,0.0.bdf2,layer2=1,portno=0 zfcp.allow_lun_scan=0
cio_ignore=all,
!condev rd.dasd=0.0.3490
```

- For installations on FCP-type disks, complete the following tasks:
 - i. Use **rd.zfcp=<adapter>,<wwpn>,<lun>** to specify the FCP disk where RHCOS is to be installed. For multipathing repeat this step for each additional path.

NOTE

When you install with multiple paths, you must enable multipathing directly after the installation, not at a later point in time, as this can cause problems.

- ii. Set the install device as: **coreos.inst.install_dev=sda**.

NOTE

If additional LUNs are configured with NPIV, FCP requires **zfcp.allow_lun_scan=0**. If you must enable **zfcp.allow_lun_scan=1** because you use a CSI driver, for example, you must configure your NPIV so that each node cannot access the boot partition of another node.

- iii. Leave all other parameters unchanged.

IMPORTANT

Additional post-installation steps are required to fully enable multipathing. For more information, see "Enabling multipathing with kernel arguments on RHCOS" in *Post-installation machine configuration tasks*.

The following is an example parameter file **worker-1.parm** for a worker node with multipathing:

```
rd.neednet=1 console=ttySCLP0 coreos.inst.install_dev=sda
coreos.live.rootfs_url=http://cl1.provide.example.com:8080/assets/rhcos-live-
rootfs.s390x.img
coreos.inst.ignition_url=http://cl1.provide.example.com:8080/ignition/worker.ign
ip=172.18.78.2::172.18.78.1:255.255.255.0::none nameserver=172.18.78.1
rd.znet=qeth,0.0.bdf0,0.0.bdf1,0.0.bdf2,layer2=1,portno=0 zfcp.allow_lun_scan=0
cio_ignore=all,
!condev
rd.zfcp=0.0.1987,0x50050763070bc5e3,0x4008400B00000000
rd.zfcp=0.0.19C7,0x50050763070bc5e3,0x4008400B00000000
rd.zfcp=0.0.1987,0x50050763071bc5e3,0x4008400B00000000
rd.zfcp=0.0.19C7,0x50050763071bc5e3,0x4008400B00000000
```

4. Transfer the initramfs, kernel, parameter files, and RHCOS images to z/VM, for example with FTP. For details about how to transfer the files with FTP and boot from the virtual reader, see [Installing under Z/VM](#).
5. Punch the files to the virtual reader of the z/VM guest virtual machine that is to become your bootstrap node.

See [PUNCH](#) in IBM Documentation.

TIP

You can use the CP PUNCH command or, if you use Linux, the **vmur** command to transfer files between two z/VM guest virtual machines.

6. Log in to CMS on the bootstrap machine.
7. IPL the bootstrap machine from the reader:

```
$ ipl c
```

See [IPL](#) in IBM Documentation.

8. Repeat this procedure for the other machines in the cluster.

12.3.11.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the **coreos-installer** command.

12.3.11.1.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

IMPORTANT

When adding networking arguments manually, you must also add the **rd.neednet=1** kernel argument to bring the network up in the initramfs.

The following table provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the **ip=**, **nameserver=**, and **bond=** kernel arguments.

NOTE

Ordering is important when adding the kernel arguments: **ip=**, **nameserver=**, and then **bond=**.

The networking options are passed to the **dracut** tool during system boot. For more information about the networking options supported by **dracut**, see the **dracut.cmdline** manual page.

Table 12.34. Networking and bonding options for ISO installations

Description	Examples
<p>To configure an IP address, either use DHCP (ip=dhcp) or set an individual static IP address (ip=<host_ip>). If setting a static IP, you must then identify the DNS server IP address (nameserver=<dns_ip>) on each node. This example sets:</p> <ul style="list-style-type: none"> • The node's IP address to 10.10.10.2 • The gateway address to 10.10.10.254 • The netmask to 255.255.255.0 • The hostname to core0.example.com • The DNS server address to 4.4.4.41 • The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically. 	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none nameserver=4.4.4.41</pre>

NOTE

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

Description	Examples
<p>Specify multiple network interfaces by specifying multiple ip= entries.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none</pre>
<p>Optional: You can configure routes to additional networks by setting an rd.route= value.</p> <p>If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.</p>	<p>To configure the default gateway:</p> <pre>ip=:10.10.10.254:::</pre> <p>To configure the route for the additional network:</p> <pre>rd.route=20.20.20.0/24:20.20.20.254:enp2s0</pre>
<p>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the enp1s0 interface has a static networking configuration and DHCP is disabled for enp2s0, which is not used.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ip=:core0.example.com:enp2s0:none</pre>

Description	Examples
<p>You can combine DHCP and static IP configurations on systems with multiple network interfaces.</p>	<pre data-bbox="817 258 1436 370">ip=enp1s0:dhcp ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp2s0:none</pre>
<p>Optional: You can configure VLANs on individual interfaces by using the vlan= parameter.</p>	<p>To configure a VLAN on a network interface and use a static IP address:</p> <pre data-bbox="849 550 1436 662">ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp2s0.100:none vlan=enp2s0.100:enp2s0</pre> <p>To configure a VLAN on a network interface and to use DHCP:</p> <pre data-bbox="849 819 1166 887">ip=enp2s0.100:dhcp vlan=enp2s0.100:enp2s0</pre>
<p>You can provide multiple DNS servers by adding a nameserver= entry for each server.</p>	<pre data-bbox="849 977 1102 1044">nameserver=1.1.1.1 nameserver=8.8.8.8</pre>
<p>Optional: Bonding multiple network interfaces to a single interface is supported using the bond= option. In these two examples:</p> <ul style="list-style-type: none"> ● The syntax for configuring a bonded interface is: bond=name[:network_interfaces] [:options] <i>name</i> is the bonding device name (bond0), <i>network_interfaces</i> represents a comma-separated list of physical (ethernet) interfaces (em1,em2), and <i>options</i> is a comma-separated list of bonding options. Enter modinfo bonding to see available options. ● When you create a bonded interface using bond=, you must specify how the IP address is assigned and other information for the bonded interface. 	<p>To configure the bonded interface to use DHCP, set the bond's IP address to dhcp. For example:</p> <pre data-bbox="849 1224 1404 1291">bond=bond0:em1,em2:mode=active-backup ip=bond0:dhcp</pre> <p>To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:</p> <pre data-bbox="849 1493 1436 1605">bond=bond0:em1,em2:mode=active-backup ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:bond0:none</pre>

Description	Examples
Optional: You can configure VLANs on bonded interfaces by using the vlan= parameter.	To configure the bonded interface with a VLAN and to use DHCP: ip=bond0.100:dhcp bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0
	To configure the bonded interface with a VLAN and to use a static IP address: ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0.100:none bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0

12.3.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

Procedure

1. Monitor the bootstrap process:

```
$ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \ ①
--log-level=info ②
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
```

```
INFO API v1.22.1 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

IMPORTANT

You must remove the bootstrap machine from the load balancer at this point.
You can also remove or reformat the bootstrap machine itself.

12.3.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- ① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

12.3.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.22.1
master-1	Ready	master	63m	v1.22.1
master-2	Ready	master	64m	v1.22.1

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-8b2br	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
csr-8vnps	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
...			

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	
Pending			
csr-c57lv	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	
Pending			
...			

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	73m	v1.22.1
master-1	Ready	master	73m	v1.22.1
master-2	Ready	master	74m	v1.22.1
worker-0	Ready	worker	11m	v1.22.1
worker-1	Ready	worker	11m	v1.22.1

NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

12.3.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.9.0	True	False	False
baremetal	4.9.0	True	False	False
cloud-credential	4.9.0	True	False	False
cluster-autoscaler	4.9.0	True	False	False
config-operator	4.9.0	True	False	False

console	4.9.0	True	False	False	26m
csi-snapshot-controller	4.9.0	True	False	False	37m
dns	4.9.0	True	False	False	37m
etcd	4.9.0	True	False	False	36m
image-registry	4.9.0	True	False	False	31m
ingress	4.9.0	True	False	False	30m
insights	4.9.0	True	False	False	31m
kube-apiserver	4.9.0	True	False	False	26m
kube-controller-manager	4.9.0	True	False	False	36m
kube-scheduler	4.9.0	True	False	False	36m
kube-storage-version-migrator	4.9.0	True	False	False	37m
machine-api	4.9.0	True	False	False	29m
machine approver	4.9.0	True	False	False	37m
machine-config	4.9.0	True	False	False	36m
marketplace	4.9.0	True	False	False	37m
monitoring	4.9.0	True	False	False	29m
network	4.9.0	True	False	False	38m
node-tuning	4.9.0	True	False	False	37m
openshift-apiserver	4.9.0	True	False	False	32m
openshift-controller-manager	4.9.0	True	False	False	30m
openshift-samples	4.9.0	True	False	False	32m
operator-lifecycle-manager	4.9.0	True	False	False	37m
operator-lifecycle-manager-catalog	4.9.0	True	False	False	37m
operator-lifecycle-manager-packageserver	4.9.0	True	False	False	32m
service-ca	4.9.0	True	False	False	38m
storage	4.9.0	True	False	False	37m

- Configure the Operators that are not available.

12.3.15.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding **disableAllDefaultSources: true** to the **OperatorHub** object:

```
$ oc patch OperatorHub cluster --type json \
-p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
```

TIP

Alternatively, you can use the web console to manage catalog sources. From the **Administration → Cluster Settings → Global Configuration → OperatorHub** page, click the **Sources** tab, where you can create, delete, disable, and enable individual sources.

12.3.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

12.3.15.2.1. Configuring registry storage for IBM Z

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster on IBM Z.
- You have provisioned persistent storage for your cluster.

IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

NOTE

When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry
```

NOTE

If the storage type is **emptyDIR**, the replica number cannot be greater than **1**.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

Example output

```
storage:
pvc:
claim:
```

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

- Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

- Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

```
$ oc edit configs.imageregistry/cluster
```

Then, change the line

```
managementState: Removed
```

to

```
managementState: Managed
```

12.3.15.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage":{"emptyDir":{}}}}'
```

WARNING

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

12.3.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.9.0	True	False	False 19m
baremetal	4.9.0	True	False	False 37m
cloud-credential	4.9.0	True	False	False 40m
cluster-autoscaler	4.9.0	True	False	False 37m
config-operator	4.9.0	True	False	False 38m
console	4.9.0	True	False	False 26m
csi-snapshot-controller	4.9.0	True	False	False 37m
dns	4.9.0	True	False	False 37m
etcd	4.9.0	True	False	False 36m
image-registry	4.9.0	True	False	False 31m
ingress	4.9.0	True	False	False 30m
insights	4.9.0	True	False	False 31m
kube-apiserver	4.9.0	True	False	False 26m
kube-controller-manager	4.9.0	True	False	False 36m
kube-scheduler	4.9.0	True	False	False 36m
kube-storage-version-migrator	4.9.0	True	False	False 37m
machine-api	4.9.0	True	False	False 29m
machine-approver	4.9.0	True	False	False 37m
machine-config	4.9.0	True	False	False 36m
marketplace	4.9.0	True	False	False 37m
monitoring	4.9.0	True	False	False 29m
network	4.9.0	True	False	False 38m
node-tuning	4.9.0	True	False	False 37m
openshift-apiserver	4.9.0	True	False	False 32m
openshift-controller-manager	4.9.0	True	False	False 30m
openshift-samples	4.9.0	True	False	False 32m
operator-lifecycle-manager	4.9.0	True	False	False 37m
operator-lifecycle-manager-catalog	4.9.0	True	False	False 37m
operator-lifecycle-manager-packageserver	4.9.0	True	False	False 32m
service-ca	4.9.0	True	False	False 38m
storage	4.9.0	True	False	False 37m

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

\$./openshift-install --dir=<installation_directory> wait-for install-complete **1**

- For <installation_directory>, specify the path to the directory that you stored the installation files in.

Example output

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- Confirm that the Kubernetes API server is communicating with the pods.

- To view a list of all pods, use the following command:

\$ oc get pods --all-namespaces

Example output

NAMESPACE	NAME	READY	STATUS
RESTARTS	AGE		
openshift-apiserver-operator	openshift-apiserver-operator-85cb746d55-zqhs8	1/1	
Running 1 9m			
openshift-apiserver	apiserver-67b9g	1/1	Running 0
3m			
openshift-apiserver	apiserver-ljcmx	1/1	Running 0
1m			
openshift-apiserver	apiserver-z25h4	1/1	Running 0
2m			
openshift-authentication-operator	authentication-operator-69d5d8bf84-vh2n8	1/1	
Running 0 5m			
...			

- View the logs for a pod that is listed in the output of the previous command by using the following command:

\$ oc logs <pod_name> -n <namespace> **1**

- Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.
See "Enabling multipathing with kernel arguments on RHCOS" in the *Post-installation machine configuration tasks* documentation for more information.
4. Register your cluster on the [Cluster registration](#) page.

12.3.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

12.3.18. Collecting debugging information

You can gather debugging information that might help you to troubleshoot and debug certain issues with an OpenShift Container Platform installation on IBM Z.

Prerequisites

- The **oc** CLI tool installed.

Procedure

1. Log in to the cluster:

```
$ oc login -u <username>
```

2. On the node you want to gather hardware information about, start a debugging container:

```
$ oc debug node/<nodename>
```

3. Change to the **/host** file system and start **toolbox**:

```
$ chroot /host  
$ toolbox
```

4. Collect the **dbginfo** data:

```
$ dbginfo.sh
```

5. You can then retrieve the data, for example, using **scp**.

Additional resources

- [How to generate SOSREPORT within OpenShift Container Platform version 4 nodes without SSH.](#)

12.3.19. Next steps

- [Customize your cluster.](#)
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by [configuring additional trust stores](#).

CHAPTER 13. INSTALLING WITH RHEL KVM ON IBM Z AND LINUXONE

13.1. PREPARING TO INSTALL WITH RHEL KVM ON IBM Z AND LINUXONE

13.1.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).

13.1.2. Choosing a method to install OpenShift Container Platform with RHEL KVM on IBM Z or LinuxONE

You can install a cluster with RHEL KVM on IBM Z or LinuxONE infrastructure that you provision, by using one of the following methods:

- **[Installing a cluster with RHEL KVM on IBM Z and LinuxONE](#)** You can install OpenShift Container Platform with KVM on IBM Z or LinuxONE infrastructure that you provision.
- **[Installing a cluster with RHEL KVM on IBM Z and LinuxONE in a restricted network](#)** You can install OpenShift Container Platform with RHEL KVM on IBM Z or LinuxONE infrastructure that you provision in a restricted or disconnected network, by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

13.2. INSTALLING A CLUSTER WITH RHEL KVM ON IBM Z AND LINUXONE

In OpenShift Container Platform version 4.9, you can install a cluster on IBM Z or LinuxONE infrastructure that you provision.

NOTE

While this document refers only to IBM Z, all information in it also applies to LinuxONE.

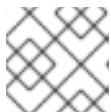

IMPORTANT

Additional considerations exist for non-bare metal platforms. Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you install an OpenShift Container Platform cluster.

13.2.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).

- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- Before you begin the installation process, you must clean the installation directory. This ensures that the required installation files are created and updated during the installation process.
- You provisioned [persistent storage using NFS](#) for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- You provisioned a RHEL Kernel Virtual Machine (KVM) system that is hosted on the logical partition (LPAR) and based on RHEL 8.3 or higher.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

13.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

13.2.3. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

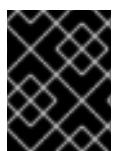

One or more KVM host machines based on RHEL 8.3 or later. Each RHEL KVM host machine must have libvirt installed and running. The virtual machines are provisioned under each RHEL KVM host machine.

13.2.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

Table 13.1. Minimum required hosts

Hosts	Description
One temporary bootstrap machine	The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.
Three control plane machines	The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.
At least two compute machines, which are also known as worker machines.	The workloads requested by OpenShift Container Platform users run on the compute machines.

IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different RHEL instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

See [Red Hat Enterprise Linux technology capabilities and limits](#).

13.2.3.2. Network connectivity requirements

The OpenShift Container Platform installer creates the Ignition files, which are necessary for all the Red Hat Enterprise Linux CoreOS (RHCOS) virtual machines. The automated installation of OpenShift Container Platform is performed by the bootstrap machine. It starts the installation of OpenShift Container Platform on each node, starts the Kubernetes cluster, and then finishes. During this bootstrap, the virtual machine must have an established network connection either through a Dynamic Host Configuration Protocol (DHCP) server or static IP address.

13.2.3.3. IBM Z network connectivity requirements

To install on IBM Z under RHEL KVM, you need:

- A RHEL KVM host configured with an OSA or RoCE network adapter.
 - Either a RHEL KVM host that is configured to use bridged networking in libvirt or MacVTap to connect the network to the guests.
- See [Types of virtual network connections](#).

13.2.3.4. Host machine resource requirements

The RHEL KVM host in your environment must meet the following requirements to host the virtual machines that you plan for the OpenShift Container Platform environment. See [Getting started with virtualization](#).

You can install OpenShift Container Platform version 4.9 on the following IBM hardware:

- IBM z15 (all models), IBM z14 (all models), IBM z13, and IBM z13s

- LinuxONE, any version

13.2.3.5. Minimum IBM Z system environment

Hardware requirements

- The equivalent of 6 IFLs, which are SMT2 enabled, for each cluster.
- At least one network connection to both connect to the **LoadBalancer** service and to serve data for traffic outside the cluster.

NOTE

You can use dedicated or shared IFLs to assign sufficient compute resources. Resource sharing is one of the key strengths of IBM Z. However, you must adjust capacity correctly on each hypervisor layer and ensure sufficient resources for every OpenShift Container Platform cluster.

IMPORTANT

Since the overall performance of the cluster can be impacted, the LPARs that are used to setup the OpenShift Container Platform clusters must provide sufficient compute capacity. In this context, LPAR weight management, entitlements, and CPU shares on the hypervisor level play an important role.

Operating system requirements

- One LPAR running RHEL 8.3 or later with KVM, which is managed via libvirt

On your RHEL KVM host, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

13.2.3.6. Minimum resource requirements

Each cluster virtual machine must meet the following minimum requirements:

Virtual Machine	Operating System	vCPU [1]	Virtual RAM	Storage	IOPS
Bootstrap	RHCOS	4	16 GB	100 GB	N/A
Control plane	RHCOS	4	16 GB	100 GB	N/A
Compute	RHCOS	2	8 GB	100 GB	N/A

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

13.2.3.7. Preferred IBM Z system environment

Hardware requirements

- 3 LPARS that each have the equivalent of 6 IFLs, which are SMT2 enabled, for each cluster.
- Two network connections to connect to both connect to the **LoadBalancer** service and to serve data for traffic outside the cluster.

Operating system requirements

- For high availability, 2 or 3 LPARs running RHEL 8.3 or later with KVM, which are managed via libvirt.

On your RHEL KVM host, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines, distributed across the RHEL KVM host machines.
- At least 6 guest virtual machines for OpenShift Container Platform compute machines, distributed across the RHEL KVM host machines.
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine.
- To ensure the availability of integral components in an overcommitted environment, increase the priority of the control plane by using **cpu_shares**. Do the same for infrastructure nodes, if they exist. See [schedinfo](#) in IBM Documentation.

13.2.3.8. Preferred resource requirements

The preferred requirements for each cluster virtual machine are:

Virtual Machine	Operating System	vCPU	Virtual RAM	Storage
Bootstrap	RHCOS	4	16 GB	120 GB
Control plane	RHCOS	8	16 GB	120 GB
Compute	RHCOS	6	8 GB	120 GB

13.2.3.9. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

Additional resources

- [Recommended host practices for IBM Z & LinuxONE environments](#)

13.2.3.10. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.

NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

13.2.3.10.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

13.2.3.10.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

**NOTE**

The RHEL KVM host must be configured to use bridged networking in libvirt or MacVTap to connect the network to the virtual machines. The virtual machines must have access to the network, which is attached to the RHEL KVM host. Virtual Networks, for example network address translation (NAT), within KVM are not a supported configuration.

Table 13.2. Ports used for all-machine to all-machine communications

Protocol	Port	Description
ICMP	N/A	Network reachability tests
TCP	1936	Metrics
	9000-9999	Host level services, including the node exporter on ports 9100-9101 and the Cluster Version Operator on port 9099 .
	10250-10259	The default ports that Kubernetes reserves
	10256	openshift-sdn
UDP	4789	VXLAN and Geneve
	6081	VXLAN and Geneve
	9000-9999	Host level services, including the node exporter on ports 9100-9101 .
TCP/UDP	30000-32767	Kubernetes node port

Table 13.3. Ports used for all-machine to control plane communications

Protocol	Port	Description
TCP	6443	Kubernetes API

Table 13.4. Ports used for control plane machine to control plane machine communications

Protocol	Port	Description
TCP	2379-2380	etcd server and peer ports

NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for [Configuring chrony time service](#).

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

Additional resources

- [Configuring chrony time service](#)

13.2.3.11. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, **<cluster_name>** is the cluster name and **<base_domain>** is the base domain that you specify in the **install-config.yaml** file. A complete DNS record takes the form: **<component>.<cluster_name>.<base_domain>..**

Table 13.5. Required DNS records

Component	Record	Description
Kubernetes API	api.<cluster_name>.<base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.
	api-int.<cluster_name>.<base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.

IMPORTANT

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.

Component	Record	Description
Routes	<code>*.apps.<cluster_name>. <base_domain>.</code>	A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <code>console-openshift-console.apps.<cluster_name>. <base_domain></code> is used as a wildcard route to the OpenShift Container Platform console.
Bootstrap machine	<code>bootstrap.<cluster_name>. <base_domain>.</code>	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.
Control plane machines	<code><master><n>. <cluster_name>. <base_domain>.</code>	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.
Compute machines	<code><worker><n>. <cluster_name>. <base_domain>.</code>	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

NOTE

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

TIP

You can use the `dig` command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

13.2.3.11.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

Example 13.1. Sample DNS zone database

```
$TTL 1W

:EOF
```

- ① Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.
- ② Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.
- ③ Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

- ④ Provides name resolution for the bootstrap machine.
- ⑤ ⑥ ⑦ Provides name resolution for the control plane machines.
- ⑧ ⑨ Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 13.2. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root (
    2019070700 ; serial
    3H ; refresh (3 hours)
    30M ; retry (30 minutes)
    2W ; expiry (2 weeks)
    1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. ①

11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. ⑦
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. ⑧
;
:EOF
```

- ① Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
- ② Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
- ③ Provides reverse DNS resolution for the bootstrap machine.
- ④ ⑤ ⑥ Provides reverse DNS resolution for the control plane machines.
- ⑦ ⑧ Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

13.2.3.12. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

- API load balancer.** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
 - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
 - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**NOTE**

Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

Table 13.6. API load balancer

Port	Back-end machines (pool members)	Internal	External	Description
6443	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.	X	X	Kubernetes API server
22623	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.	X		Machine config server

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the **/readyz** endpoint to the removal of the API server instance from the pool. Within the time frame after **/readyz** returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. Application ingress load balancer. Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 13.7. Application ingress load balancer

Port	Back-end machines (pool members)	Internal	External	Description
443	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTPS traffic
80	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTP traffic

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

NOTE

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

13.2.3.12.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an **/etc/haproxy/haproxy.cfg** configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 13.3. Sample API and application ingress load balancer configuration

```

global
  log    127.0.0.1 local2
  pidfile /var/run/haproxy.pid
  maxconn 4000
  daemon
defaults
  mode      http
  log       global
  option    dontlognull
  option http-server-close
  option    redispatch
  retries   3
  timeout http-request 10s
  timeout queue     1m
  timeout connect    10s
  timeout client     1m
  timeout server     1m
  timeout http-keep-alive 10s
  timeout check      10s
  maxconn   3000

  bind *:1936
  mode      http
  log       global
  maxconn 10
  stats enable
  stats hide-version
  stats refresh 30s
  stats show-node
  stats show-desc Stats for ocp4 cluster ①
  stats auth admin:ocp4
  stats uri /stats
listen api-server-6443 ②
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup ③
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623 ④
  bind *:22623
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup ⑤
  server master0 master0.ocp4.example.com:22623 check inter 1s
  server master1 master1.ocp4.example.com:22623 check inter 1s
  server master2 master2.ocp4.example.com:22623 check inter 1s

```

```

listen ingress-router-443 6
  bind *:443
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:443 check inter 1s
  server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80 7
  bind *:80
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:80 check inter 1s
  server worker1 worker1.ocp4.example.com:80 check inter 1s

```

- 1** In the example, the cluster name is **ocp4**.
- 2** Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
- 3** **5** The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.
- 4** Port **22623** handles the machine config server traffic and points to the control plane machines.
- 6** Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
- 7** Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltpu** on the HAProxy node.

NOTE

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy_connect_any=1**.

13.2.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in

preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

Prerequisites

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
 - a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
 - b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

NOTE

If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

- c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the *Setting the cluster node hostnames through DHCP* section for details about hostname considerations.

NOTE

If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Choose to perform either a fast track installation of Red Hat Enterprise Linux CoreOS (RHCOS) or a full installation of Red Hat Enterprise Linux CoreOS (RHCOS). For the full installation, you must set up an HTTP or HTTPS server to provide Ignition files and install images to the cluster nodes. For the fast track installation an HTTP or HTTPS server is not required, however, a DHCP server is required. See sections "Fast-track installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines" and "Full installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines".

3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.
4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.
5. Setup the required DNS infrastructure for your cluster.
 - a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
 - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.
6. Validate your DNS configuration.
 - a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
 - b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.

See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.
7. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

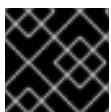

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

13.2.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
 - a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> 1
```

- 1 Replace **<nameserver_ip>** with the IP address of the nameserver, **<cluster_name>** with your cluster name, and **<base_domain>** with your base domain name.

Example output

```
api.ocp4.example.com. 0 IN A 192.168.1.5
```

- b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

```
api-int.ocp4.example.com. 0 IN A 192.168.1.5
```

- c. Test an example ***.apps.<cluster_name>.<base_domain>** DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

```
random.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace **random** with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

-
- d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

- e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
- 2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.
- a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. ①  
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. ②
```

- ① Provides the record name for the Kubernetes internal API.
- ② Provides the record name for the Kubernetes API.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

- b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

- c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

13.2.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> ①
```

1. Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> ①
```

- ① Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

13.2.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the [Infrastructure Provider](#) page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. From the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

13.2.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.9. Download and install the new version of **oc**.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.9 Linux Client** entry and save the file.
4. Unpack the archive:

```
$ tar xvzf <file>
```

5. Place the **oc** binary in a directory that is on your **PATH**.

To check your **PATH**, execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.9 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.

To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.9 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.

To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

13.2.9. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation_directory>**.

NOTE

You must name this configuration file **install-config.yaml**.

NOTE

For some platform types, you can alternatively run **./openshift-install create install-config --dir=<installation_directory>** to generate an **install-config.yaml** file. You can provide details about your cluster configuration at the prompts.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

13.2.9.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized **install-config.yaml** installation configuration file that describes the details for your environment.

NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

IMPORTANT

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

13.2.9.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 13.8. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>. <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}} .	String of lowercase letters, hyphens (-), and periods (.), such as dev .

Parameter	Description	Values
platform	The configuration for the specific platform upon which to perform the installation: aws , baremetal , azure , openstack , ovirt , vsphere , or <code>{}</code> . For additional information about platform . <platform> parameters, consult the table for your specific platform that follows.	Object
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths":{ "cloud.openshift.com":{ "auth":"b3Blb=", "email":"you@example.com" }, "quay.io":{ "auth":"b3Blb=", "email":"you@example.com" } } }</pre>

13.2.9.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 13.9. Network parameters

Parameter	Description	Values
networking	The configuration for the cluster network.	<p>Object</p>  <p>NOTE</p> <p>You cannot modify parameters specified by the networking object after installation.</p>

Parameter	Description	Values
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23 . If you specify multiple IP address blocks, the blocks must not overlap.	An array of objects. For example: <pre>networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</pre>
networking.clusterNetwork.cidr	Required if you use networking.clusterNetwork . An IP address block. An IPv4 network.	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{32-23} - 2$) pod IP addresses.	A subnet prefix. The default value is 23 .
networking.serviceNetwork	The IP address block for services. The default value is 172.30.0.0/16 . The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.	An array with an IP address block in CIDR format. For example: <pre>networking: serviceNetwork: - 172.30.0.0/16</pre>
networking.machineNetwork	The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.	An array of objects. For example: <pre>networking: machineNetwork: - cidr: 10.0.0.0/16</pre>

Parameter	Description	Values
networking.machineNetwork.cidr	Required if you use networking.machineNetwork . An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24 .	<p>An IP network block in CIDR notation. For example, 10.0.0.0/16.</p>  <p>NOTE Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.</p>

13.2.9.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 13.10. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).	String

Parameter	Description	Values
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere , or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).	String

Parameter	Description	Values
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	 IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws , azure , gcp , openstack , ovirt , vsphere , or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.	Mint, Passthrough, Manual , or an empty string ("").
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>NOTE</p> <p>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the <i>Cloud Credential Operator</i> entry in the <i>Red Hat Operators</i> reference content.</p>	false or true
imageContentSources	 <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.

Parameter	Description	Values
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.	Internal or External . The default value is External . Setting this field to Internal is not supported on non-cloud platforms.
sshKey	The SSH key or keys to authenticate access your cluster machines. 	One or more keys. For example: sshKey: <key1> <key2> <key3>

13.2.9.2. Sample `install-config.yaml` file for IBM Z

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```

apiVersion: v1
baseDomain: example.com ①
compute: ②
- hyperthreading: Enabled ③
  name: worker
  replicas: 0 ④
  architecture : s390x
controlPlane: ⑤
  hyperthreading: Enabled ⑥
  name: master
  replicas: 3 ⑦
  architecture : s390x
metadata:
  name: test ⑧
networking:
```

```

clusterNetwork:
- cidr: 10.128.0.0/14 9
  hostPrefix: 23 10
networkType: OpenShiftSDN
serviceNetwork: 11
- 172.30.0.0/16
platform:
  none: {} 12
  fips: false 13
  pullSecret: '{"auths": ...}' 14
  sshKey: 'ssh-ed25519 AAAA...' 15

```

1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2 **5** The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, **-**, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

3 **6** Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not available on your OpenShift Container Platform nodes, the **hyperthreading** parameter has no effect.

IMPORTANT

If you disable **hyperthreading**, whether on your OpenShift Container Platform nodes or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

4 You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

7 The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

- 8 The cluster name that you specified in your DNS records.
- 9 A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.
- 10 The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to **23**, then each node is assigned a /23 subnet out of the given **cidr**, which allows for 510 ($2^{(32 - 23)} - 2$) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.
- 11 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.
- 12 You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Z infrastructure.

WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as [installing a cluster on any platform](#), and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.
2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

- 13 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

- 14 The pull secret that you obtained from the [Red Hat OpenShift Cluster Manager](#) site. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.
- 15 The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

13.2.9.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the **ec2.<region>.amazonaws.com**, **elasticloadbalancing.<region>.amazonaws.com**, and **s3.<region>.amazonaws.com** endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

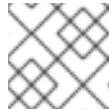

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ①
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
  noProxy: example.com ③
  additionalTrustBundle: | ④
    -----BEGIN CERTIFICATE-----
```

```
<MY_TRUSTED_CA_CERT>
-----END CERTIFICATE-----
```

...

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpProxy** value.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpsProxy** value.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace to hold the additional CA certificates. If you provide **additionalTrustBundle** and at least one proxy setting, the **Proxy** object is configured to reference the **user-ca-bundle** config map in the **trustedCA** field. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges the contents specified for the **trustedCA** parameter with the RHCOS trust bundle. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE

The installation program does not support the proxy **readinessEndpoints** field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

13.2.9.4. Configuring a three-node cluster

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing **install-config.yaml** file.

Procedure

- Ensure that the number of compute replicas is set to **0** in your **install-config.yaml** file, as shown in the following **compute** stanza:

```
compute:
- name: worker
  platform: {}
  replicas: 0
```

NOTE

You must set the value of the **replicas** parameter for the compute machines to **0** when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

NOTE

The preferred resource for control plane nodes is six vCPUs and 21 GB. For three control plane nodes this is the memory + vCPU equivalent of a minimum five-node cluster. You should back the three nodes, each installed on a 120 GB disk, with three IFLs that are SMT2 enabled. The minimum tested setup is three vCPUs and 10 GB on a 120 GB disk for each control plane node.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.
- When you create the Kubernetes manifest files in the following procedure, ensure that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file is set to **true**. This enables your application workloads to run on the control plane nodes.
- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

13.2.10. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named **cluster**. The CR specifies the fields for the **Network** API in the **operator.openshift.io** API group.

The CNO configuration inherits the following fields during cluster installation from the **Network** API in the **Network.config.openshift.io** API group and these fields cannot be changed:

clusterNetwork

IP address pools from which pod IP addresses are allocated.

serviceNetwork

IP address pool for services.

defaultNetwork.type

Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

13.2.10.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

Table 13.11. Cluster Network Operator configuration object

Field	Type	Description
metadata.name	string	The name of the CNO object. This name is always cluster .
spec.clusterNetwork	array	<p>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</p> <pre>spec: clusterNetwork: - cidr: 10.128.0.0/19 hostPrefix: 23 - cidr: 10.128.32.0/19 hostPrefix: 23</pre> <p>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</p>
spec.serviceNetwork	array	<p>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:</p> <pre>spec: serviceNetwork: - 172.30.0.0/14</pre> <p>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</p>
spec.defaultNetwork	object	Configures the Container Network Interface (CNI) cluster network provider for the cluster network.

Field	Type	Description
spec.kubeProxyConfig	object	The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

defaultNetwork object configuration

The values for the **defaultNetwork** object are defined in the following table:

Table 13.12. **defaultNetwork** object

Field	Type	Description
type	string	<p>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</p>  <p>NOTE</p> <p>OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.</p>
openshiftSDNConfig	object	This object is only valid for the OpenShift SDN cluster network provider.
ovnKubernetesConfig	object	This object is only valid for the OVN-Kubernetes cluster network provider.

Configuration for the OpenShift SDN CNI cluster network provider

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

Table 13.13. **openshiftSDNConfig** object

Field	Type	Description
mode	string	<p>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy.</p> <p>The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</p>

Field	Type	Description
mtu	integer	<p>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.</p> <p>This value cannot be changed after cluster installation.</p>
vxlanPort	integer	<p>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.</p> <p>If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.</p> <p>On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</p>

Example OpenShift SDN configuration

```
defaultNetwork:
type: OpenShiftSDN
openshiftSDNConfig:
  mode: NetworkPolicy
  mtu: 1450
  vxlanPort: 4789
```

Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

Table 13.14. `ovnKubernetesConfig` object

Field	Type	Description
mtu	integer	<p>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.</p> <p>This value cannot be changed after cluster installation.</p>
genevePort	integer	The port to use for all Geneve packets. The default value is 6081 . This value cannot be changed after cluster installation.
policyAuditConfig	object	Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.

Table 13.15. **policyAuditConfig** object

Field	Type	Description
rateLimit	integer	The maximum number of messages to generate every second per node. The default value is 20 messages per second.
maxFileSize	integer	The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.
destination	string	<p>One of the following additional audit log targets:</p> <p>libc The libc syslog() function of the journald process on the host.</p> <p>udp:<host>:<port> A syslog server. Replace <host>:<port> with the host and port of the syslog server.</p> <p>unix:<file> A Unix Domain Socket file specified by <file>.</p> <p>null Do not send the audit logs to any additional target.</p>

Field	Type	Description
syslogFacility	string	The syslog facility, such as kern , as defined by RFC5424. The default value is local0 .

Example OVN-Kubernetes configuration

```
defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
```

kubeProxyConfig object configuration

The values for the **kubeProxyConfig** object are defined in the following table:

Table 13.16. **kubeProxyConfig** object

Field	Type	Description
iptablesSyncPeriod	string	<p>The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</p> <p> NOTE</p> <p>Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary.</p>
proxyArguments.iptables-min-sync-period	array	<p>The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s, m, and h and are described in the Go time package. The default value is:</p> <pre>kubeProxyConfig: proxyArguments: iptables-min-sync-period: - 0s</pre>

13.2.11. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the [client image mirror](#). The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the **install-config.yaml** installation configuration file.

Procedure

- 1 Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

Example output

```
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift
```

- 1 For **<installation_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

WARNING

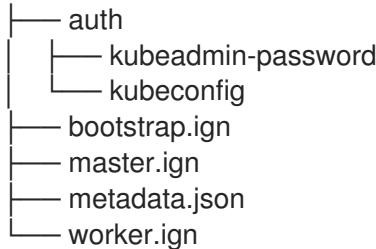

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

2. Check that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
 - a. Open the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file.
 - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
 - c. Save and exit the file.
3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory> ①
```

- ① For **<installation_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation_directory>/auth** directory:

13.2.12. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Z infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) as Red Hat Enterprise Linux (RHEL) guest virtual machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

You can perform a fast-track installation of RHCOS that uses a prepackaged QEMU copy-on-write (QCOW2) disk image. Alternatively, you can perform a full installation on a new QCOW2 disk image.

13.2.12.1. Fast-track installation by using a prepackaged QCOW2 disk image

Complete the following steps to create the machines in a fast-track installation of Red Hat Enterprise Linux CoreOS (RHCOS), importing a prepackaged Red Hat Enterprise Linux CoreOS (RHCOS) QEMU copy-on-write (QCOW2) disk image.

Prerequisites

- At least 1 LPAR running RHEL 8.3 with KVM, referred to as RHEL KVM host in this procedure.

- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
- A DHCP server that provides IP addresses.

Procedure

1. Obtain the RHEL QEMU copy-on-write (QCOW2) disk image file from the [Product Downloads](#) page on the Red Hat Customer Portal or from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

2. Download the QCOW2 disk image and Ignition files to a common directory on the RHEL KVM host.

For example: `/var/lib/libvirt/images`

NOTE

The Ignition files are generated by the OpenShift Container Platform installer.

3. Create a new disk image with the QCOW2 disk image backing file for each KVM guest node.

```
$ qemu-img create -f qcow2 -F qcow2 -b /var/lib/libvirt/images/{source_rhcos_qemu} /var/lib/libvirt/images/{vmname}.qcow2 {size}
```

4. Create the new KVM guest nodes using the Ignition file and the new disk image.

```
$ virt-install --noautoconsole \
--connect qemu:///system \
--name {vn_name} \
--memory {memory} \
--vcpus {vcpus} \
--disk {disk} \
--import \
--network network={network},mac={mac} \
--qemu-commandline="--drive \
if=none,id=ignition,format=raw,file={ign_file},readonly=on -device virtio-blk,serial=ignition,drive=ignition"
```

13.2.12.2. Full installation on a new QCOW2 disk image

Complete the following steps to create the machines in a full installation on a new QEMU copy-on-write (QCOW2) disk image.

Prerequisites

- At least 1 LPAR running RHEL 8.3 with KVM, referred to as RHEL KVM host in this procedure.

- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
- An HTTP or HTTPS server is set up.

Procedure

1. Obtain the RHEL kernel, initramfs, and rootfs files from the [Product Downloads](#) page on the Red Hat Customer Portal or from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- kernel: **rhcoss-<version>-live-kernel-<architecture>**
 - initramfs: **rhcoss-<version>-live-initramfs.<architecture>.img**
 - rootfs: **rhcoss-<version>-live-rootfs.<architecture>.img**
2. Move the downloaded RHEL live kernel, initramfs, and rootfs as well as the Ignition files to an HTTP or HTTPS server before you launch **virt-install**.

NOTE

The Ignition files are generated by the OpenShift Container Platform installer.

3. Create the new KVM guest nodes using the RHEL kernel, initramfs, and Ignition files, the new disk image, and adjusted parm line arguments.
 - For **--location**, specify the location of the kernel/initrd on the HTTP or HTTPS server.
 - For **coreos.inst.ignition_url=**, specify the Ignition file for the machine role. Use **bootstrap.ign**, **master.ign**, or **worker.ign**. Only HTTP and HTTPS protocols are supported.
 - For **coreos.live.rootfs_url=**, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

```
$ virt-install \
--connect qemu:///system \
--name {vn_name} \
--vcpus {vcpus} \
--memory {memory_mb} \
--disk {vn_name}.qcow2,size={image_size| default(10,true)} \
--network network={virt_network_parm} \
--boot hd \
--location {media_location},kernel={rhcoss_kernel},initrd={rhcoss_initrd} \
--extra-args "rd.neednet=1 coreos.inst=yes coreos.inst.install_dev=vda"
```

```
coreos.live.rootfs_url={rhcos_liveos} ip={ip}:{default_gateway}:{subnet_mask_length}: {vn_name}:enc1:none:{MTU} nameserver={dns} coreos.inst.ignition_url={rhcos_ign}" \
--noautoconsole \
--wait
```

13.2.13. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

```
$ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \ ①
--log-level=info ②
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.22.1 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

IMPORTANT

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

13.2.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- ① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

13.2.15. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.22.1
master-1	Ready	master	63m	v1.22.1
master-2	Ready	master	64m	v1.22.1

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

- Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-mddf5	20m	system:node:master-01.example.com	Approved,Issued
csr-z5rln	16m	system:node:worker-21.example.com	Approved,Issued

- If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

NOTE

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	Pending
csr-c57lv	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	Pending
	...		

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs oc adm certificate approve
```

- After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	73m	v1.22.1

```
master-1 Ready master 73m v1.22.1
master-2 Ready master 74m v1.22.1
worker-0 Ready worker 11m v1.22.1
worker-1 Ready worker 11m v1.22.1
```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

13.2.16. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.9.0	True	False	False 19m
baremetal	4.9.0	True	False	False 37m

openshift-samples	4.9.0	True	False	False	32m
operator-lifecycle-manager	4.9.0	True	False	False	37m
operator-lifecycle-manager-catalog	4.9.0	True	False	False	37m
operator-lifecycle-manager-packageserver	4.9.0	True	False	False	32m
service-ca	4.9.0	True	False	False	38m
storage	4.9.0	True	False	False	37m

- Configure the Operators that are not available.

13.2.16.1. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

13.2.16.1.1. Configuring registry storage for IBM Z

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster on IBM Z.
- You have provisioned persistent storage for your cluster.

IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

Procedure

- To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

**NOTE**

When using shared storage, review your security settings to prevent outside access.

- Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry
```

**NOTE**

If the storage type is **emptyDIR**, the replica number cannot be greater than **1**.

- Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

Example output

```
storage:  
pvc:  
claim:
```

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

- Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

- Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

```
$ oc edit configs.imageregistry/cluster
```

Then, change the line

```
managementState: Removed
```

to

```
managementState: Managed
```

13.2.16.1.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage":{"emptyDir":{}}}}'
```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

13.2.17. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.9.0	True	False	False 19m
baremetal	4.9.0	True	False	False 37m
cloud-credential	4.9.0	True	False	False 40m
cluster-autoscaler	4.9.0	True	False	False 37m
config-operator	4.9.0	True	False	False 38m
console	4.9.0	True	False	False 26m
csi-snapshot-controller	4.9.0	True	False	False 37m
dns	4.9.0	True	False	False 37m
etcd	4.9.0	True	False	False 36m
image-registry	4.9.0	True	False	False 31m
ingress	4.9.0	True	False	False 30m
insights	4.9.0	True	False	False 31m
kube-apiserver	4.9.0	True	False	False 26m
kube-controller-manager	4.9.0	True	False	False 36m

kube-scheduler	4.9.0	True	False	False	36m
kube-storage-version-migrator	4.9.0	True	False	False	37m
machine-api	4.9.0	True	False	False	29m
machine approver	4.9.0	True	False	False	37m
machine-config	4.9.0	True	False	False	36m
marketplace	4.9.0	True	False	False	37m
monitoring	4.9.0	True	False	False	29m
network	4.9.0	True	False	False	38m
node-tuning	4.9.0	True	False	False	37m
openshift-apiserver	4.9.0	True	False	False	32m
openshift-controller-manager	4.9.0	True	False	False	30m
openshift-samples	4.9.0	True	False	False	32m
operator-lifecycle-manager	4.9.0	True	False	False	37m
operator-lifecycle-manager-catalog	4.9.0	True	False	False	37m
operator-lifecycle-manager-packageserver	4.9.0	True	False	False	32m
service-ca	4.9.0	True	False	False	38m
storage	4.9.0	True	False	False	37m

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete ①
```

- ① For <installation_directory>, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.

- a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

Example output

NAMESPACE	NAME	READY	STATUS
RESTARTS	AGE		
openshift-apiserver-operator	openshift-apiserver-operator-85cb746d55-zqhs8	1/1	
Running 1	9m		
openshift-apiserver	apiserver-67b9g	1/1	Running 0
3m			
openshift-apiserver	apiserver-ljcmx	1/1	Running 0
1m			
openshift-apiserver	apiserver-z25h4	1/1	Running 0
2m			
openshift-authentication-operator	authentication-operator-69d5d8bf84-vh2n8	1/1	
Running 0	5m		
...			

- b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> ①
```

- ① Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.
See "Enabling multipathing with kernel arguments on RHCOS" in the *Post-installation machine configuration tasks* documentation for more information.

13.2.18. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

13.2.19. Collecting debugging information

You can gather debugging information that might help you to troubleshoot and debug certain issues with an OpenShift Container Platform installation on IBM Z.

Prerequisites

- The **oc** CLI tool installed.

Procedure

1. Log in to the cluster:

```
$ oc login -u <username>
```

2. On the node you want to gather hardware information about, start a debugging container:

```
$ oc debug node/<nodename>
```

3. Change to the `/host` file system and start **toolbox**:

```
$ chroot /host  
$ toolbox
```

4. Collect the **dbginfo** data:

```
$ dbginfo.sh
```

5. You can then retrieve the data, for example, using **scp**.

Additional resources

- [How to generate SOSREPORT within OpenShift4 nodes without SSH](#) .

13.2.20. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#) .

13.3. INSTALLING A CLUSTER WITH RHEL KVM ON IBM Z AND LINUXONE IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.9, you can install a cluster on IBM Z and LinuxONE infrastructure that you provision in a restricted network.

NOTE

While this document refers to only IBM Z, all information in it also applies to LinuxONE.

IMPORTANT

Additional considerations exist for non-bare metal platforms. Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you install an OpenShift Container Platform cluster.

13.3.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).

- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [created a registry on your mirror host](#) and obtained the **imageContentSources** data for your version of OpenShift Container Platform.
- You must move or remove any existing installation files, before you begin the installation process. This ensures that the required installation files are created and updated during the installation process.

IMPORTANT

Ensure that installation steps are done from a machine with access to the installation media.

- You provisioned [persistent storage using NFS](#) for your cluster. To deploy a private image registry, your storage must provide **ReadWriteMany** access modes.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- You provisioned a RHEL Kernel Virtual Machine (KVM) system that is hosted on the logical partition (LPAR) and based on RHEL 8.3 or higher.

NOTE

Be sure to also review this site list if you are configuring a proxy.

13.3.2. About installations in restricted networks

In OpenShift Container Platform 4.9, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require internet access, so you might still require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

13.3.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

13.3.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

13.3.4. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

One or more KVM host machines based on RHEL 8.3 or later. Each RHEL KVM host machine must have libvirt installed and running. The virtual machines are provisioned under each RHEL KVM host machine.

13.3.4.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

Table 13.17. Minimum required hosts

Hosts	Description
One temporary bootstrap machine	The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.
Three control plane machines	The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.

Hosts	Description
At least two compute machines, which are also known as worker machines.	The workloads requested by OpenShift Container Platform users run on the compute machines.

IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different RHEL instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

See [Red Hat Enterprise Linux technology capabilities and limits](#).

13.3.4.2. Network connectivity requirements

The OpenShift Container Platform installer creates the Ignition files, which are necessary for all the Red Hat Enterprise Linux CoreOS (RHCOS) virtual machines. The automated installation of OpenShift Container Platform is performed by the bootstrap machine. It starts the installation of OpenShift Container Platform on each node, starts the Kubernetes cluster, and then finishes. During this bootstrap, the virtual machine must have an established network connection either through a Dynamic Host Configuration Protocol (DHCP) server or static IP address.

13.3.4.3. IBM Z network connectivity requirements

To install on IBM Z under RHEL KVM, you need:

- A RHEL KVM host configured with an OSA or RoCE network adapter.
- Either a RHEL KVM host that is configured to use bridged networking in libvirt or MacVTap to connect the network to the guests.
See [Types of virtual network connections](#).

13.3.4.4. Host machine resource requirements

The RHEL KVM host in your environment must meet the following requirements to host the virtual machines that you plan for the OpenShift Container Platform environment. See [Getting started with virtualization](#).

You can install OpenShift Container Platform version 4.9 on the following IBM hardware:

- IBM z15 (all models), IBM z14 (all models), IBM z13, and IBM z13s
- LinuxONE, any version

13.3.4.5. Minimum IBM Z system environment

Hardware requirements

- The equivalent of 6 IFLs, which are SMT2 enabled, for each cluster.

- At least one network connection to both connect to the **LoadBalancer** service and to serve data for traffic outside the cluster.

NOTE

You can use dedicated or shared IFLs to assign sufficient compute resources. Resource sharing is one of the key strengths of IBM Z. However, you must adjust capacity correctly on each hypervisor layer and ensure sufficient resources for every OpenShift Container Platform cluster.

IMPORTANT

Since the overall performance of the cluster can be impacted, the LPARs that are used to setup the OpenShift Container Platform clusters must provide sufficient compute capacity. In this context, LPAR weight management, entitlements, and CPU shares on the hypervisor level play an important role.

Operating system requirements

- One LPAR running RHEL 8.3 or later with KVM, which is managed via libvirt

On your RHEL KVM host, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

13.3.4.6. Minimum resource requirements

Each cluster virtual machine must meet the following minimum requirements:

Virtual Machine	Operating System	vCPU [1]	Virtual RAM	Storage	IOPS
Bootstrap	RHCOS	4	16 GB	100 GB	N/A
Control plane	RHCOS	4	16 GB	100 GB	N/A
Compute	RHCOS	2	8 GB	100 GB	N/A

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

13.3.4.7. Preferred IBM Z system environment

Hardware requirements

- 3 LPARS that each have the equivalent of 6 IFLs, which are SMT2 enabled, for each cluster.
- Two network connections to connect to both connect to the **LoadBalancer** service and to serve data for traffic outside the cluster.

Operating system requirements

- For high availability, 2 or 3 LPARs running RHEL 8.3 or later with KVM, which are managed via libvirt.

On your RHEL KVM host, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines, distributed across the RHEL KVM host machines.
- At least 6 guest virtual machines for OpenShift Container Platform compute machines, distributed across the RHEL KVM host machines.
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine.
- To ensure the availability of integral components in an overcommitted environment, increase the priority of the control plane by using **cpu_shares**. Do the same for infrastructure nodes, if they exist. See [schedinfo](#) in IBM Documentation.

13.3.4.8. Preferred resource requirements

The preferred requirements for each cluster virtual machine are:

Virtual Machine	Operating System	vCPU	Virtual RAM	Storage
Bootstrap	RHCOS	4	16 GB	120 GB
Control plane	RHCOS	8	16 GB	120 GB
Compute	RHCOS	6	8 GB	120 GB

13.3.4.9. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

Additional resources

- [Recommended host practices for IBM Z & LinuxONE environments](#)

13.3.4.10. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

The machines are configured with static IP addresses. No DHCP server is required. Ensure that the machines have persistent IP addresses and hostnames.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

13.3.4.10.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 13.18. Ports used for all-machine to all-machine communications

Protocol	Port	Description
ICMP	N/A	Network reachability tests
TCP	1936	Metrics
	9000-9999	Host level services, including the node exporter on ports 9100-9101 and the Cluster Version Operator on port 9099 .
	10250-10259	The default ports that Kubernetes reserves
	10256	openshift-sdn
UDP	4789	VXLAN and Geneve
	6081	VXLAN and Geneve
	9000-9999	Host level services, including the node exporter on ports 9100-9101 .
TCP/UDP	30000-32767	Kubernetes node port

Table 13.19. Ports used for all-machine to control plane communications

Protocol	Port	Description
TCP	6443	Kubernetes API

Table 13.20. Ports used for control plane machine to control plane machine communications

Protocol	Port	Description
TCP	2379-2380	etcd server and peer ports

NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

Additional resources

- [Configuring chrony time service](#)

13.3.4.11. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, **<cluster_name>** is the cluster name and **<base_domain>** is the base domain that you specify in the **install-config.yaml** file. A complete DNS record takes the form: **<component>.<cluster_name>.<base_domain>..**

Table 13.21. Required DNS records

Component	Record	Description

Component	Record	Description
Kubernetes API	api.<cluster_name>. <base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.
	api-int.<cluster_name>. <base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.
		 <p>IMPORTANT</p> <p>The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</p>
Routes	*.apps.<cluster_name>. <base_domain>.	<p>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</p> <p>For example, console-openshift-console.apps.<cluster_name>. <base_domain> is used as a wildcard route to the OpenShift Container Platform console.</p>
Bootstrap machine	bootstrap.<cluster_name>. <base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.
Control plane machines	<master><n>. <cluster_name>. <base_domain>.	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.
Compute machines	<worker><n>. <cluster_name>. <base_domain>.	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

NOTE

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

TIP

You can use the **dig** command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

13.3.4.11.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is **ocp4** and the base domain is **example.com**.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

Example 13.4. Sample DNS zone database

```
$TTL 1W
@ IN SOA ns1.example.com. root (

worker1.ocp4.example.com. IN A 192.168.1.7 ⑨
;
;EOF
```

1 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

- ② Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.
- ③ Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

- ④ Provides name resolution for the bootstrap machine.
- ⑤ ⑥ ⑦ Provides name resolution for the control plane machines.
- ⑧ ⑨ Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 13.5. Sample DNS zone database for reverse records

```

```

- 1 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
- 2 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
- 3 Provides reverse DNS resolution for the bootstrap machine.
- 4 5 6 Provides reverse DNS resolution for the control plane machines.
- 7 8 Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

13.3.4.12. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer:** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
 - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
 - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**NOTE**

Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

Table 13.22. API load balancer

Port	Back-end machines (pool members)	Internal	External	Description
6443	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.	X	X	Kubernetes API server

Port	Back-end machines (pool members)	Internal	External	Description
22623	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.	X		Machine config server

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer.** Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 13.23. Application ingress load balancer

Port	Back-end machines (pool members)	Internal	External	Description
443	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTPS traffic
80	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTP traffic

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

13.3.4.12.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an **/etc/haproxy/haproxy.cfg** configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 13.6. Sample API and application ingress load balancer configuration

```
global
  log    127.0.0.1 local2
  pidfile /var/run/haproxy.pid
  maxconn 4000
  daemon
defaults
  mode      http
  log       global
  option    dontlognull
  option http-server-close
  option    redispatch
  retries   3
  timeout http-request 10s
  timeout queue     1m
  timeout connect   10s
  timeout client    1m
  timeout server    1m
  timeout http-keep-alive 10s
  timeout check     10s
  maxconn   3000
frontend stats
  bind *:1936
  mode      http
  log       global
  maxconn 10
  stats enable
```

```

stats hide-version
stats refresh 30s
stats show-node
stats show-desc Stats for ocp4 cluster ①
stats auth admin:ocp4
stats uri /stats
listen api-server-6443 ②
bind *:6443
mode tcp
server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup ③
server master0 master0.ocp4.example.com:6443 check inter 1s
server master1 master1.ocp4.example.com:6443 check inter 1s
server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623 ④
bind *:22623
mode tcp
server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup ⑤
server master0 master0.ocp4.example.com:22623 check inter 1s
server master1 master1.ocp4.example.com:22623 check inter 1s
server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443 ⑥
bind *:443
mode tcp
balance source
server worker0 worker0.ocp4.example.com:443 check inter 1s
server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80 ⑦
bind *:80
mode tcp
balance source
server worker0 worker0.ocp4.example.com:80 check inter 1s
server worker1 worker1.ocp4.example.com:80 check inter 1s

```

- ① In the example, the cluster name is **ocp4**.
- ② Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
- ③ ⑤ The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.
- ④ Port **22623** handles the machine config server traffic and points to the control plane machines.
- ⑥ Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
- ⑦ Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltpu** on the HAProxy node.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy_connect_any=1**.

13.3.5. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, preparing a web server for the Ignition files, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

Prerequisites

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

Procedure

1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Choose to perform either a fast track installation of Red Hat Enterprise Linux CoreOS (RHCOS) or a full installation of Red Hat Enterprise Linux CoreOS (RHCOS). For the full installation, you must set up an HTTP or HTTPS server to provide Ignition files and install images to the cluster nodes. For the fast track installation an HTTP or HTTPS server is not required, however, a DHCP server is required. See sections “Fast-track installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines” and “Full installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines”.
4. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.
5. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.

6. Setup the required DNS infrastructure for your cluster.
 - a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
 - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.
7. Validate your DNS configuration.
 - a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
 - b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.

See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.
8. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

13.3.6. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
 - a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> 1
```

- 1 Replace <nameserver_ip> with the IP address of the nameserver, <cluster_name> with your cluster name, and <base_domain> with your base domain name.

Example output

```
api.ocp4.example.com. 0 IN A 192.168.1.5
```

- b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

```
api-int.ocp4.example.com. 0 IN A 192.168.1.5
```

- c. Test an example *.apps.<cluster_name>.<base_domain> DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

```
random.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace **random** with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

- d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

bootstrap.ocp4.example.com. 0 IN A 192.168.1.96

- e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.
 - a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. ①
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. ②
```

- ① Provides the record name for the Kubernetes internal API.
- ② Provides the record name for the Kubernetes API.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

- b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

- c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

13.3.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **./openshift-install gather** command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the **./openshift-install gather** command.

NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> ①
```

- ① Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

13.3.8. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation_directory>**.

NOTE

You must name this configuration file **install-config.yaml**.

NOTE

For some platform types, you can alternatively run `./openshift-install create install-config --dir=<installation_directory>` to generate an **install-config.yaml** file. You can provide details about your cluster configuration at the prompts.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

13.3.8.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized **install-config.yaml** installation configuration file that describes the details for your environment.

NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

IMPORTANT

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

13.3.8.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 13.24. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>, <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}} .	String of lowercase letters, hyphens (-), and periods (.), such as dev .
platform	The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere , or {} . For additional information about platform , <platform> parameters, consult the table for your specific platform that follows.	Object

Parameter	Description	Values
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths": { "cloud.openshift.com": { "auth": "b3Blb=", "email": "you@example.com" }, "quay.io": { "auth": "b3Blb=", "email": "you@example.com" } } }</pre>

13.3.8.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 13.25. Network parameters

Parameter	Description	Values
networking	The configuration for the cluster network.	Object  NOTE You cannot modify parameters specified by the networking object after installation.
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23 . If you specify multiple IP address blocks, the blocks must not overlap.	An array of objects. For example: <pre>networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</pre>

Parameter	Description	Values
networking.clusterNetwork.cidr	Required if you use networking.clusterNetwork . An IP address block. An IPv4 network.	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{(32 - 23)} - 2$) pod IP addresses.	A subnet prefix. The default value is 23 .
networking.serviceNetwork	The IP address block for services. The default value is 172.30.0.0/16 . The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.	An array with an IP address block in CIDR format. For example: networking: serviceNetwork: - 172.30.0.0/16
networking.machineNetwork	The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.	An array of objects. For example: networking: machineNetwork: - cidr: 10.0.0.0/16
networking.machineNetwork.cidr	Required if you use networking.machineNetwork . An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24 .	An IP network block in CIDR notation. For example, 10.0.0.0/16 .

**NOTE**

Set the **networking.machineNetwork** to match the CIDR that the preferred NIC resides in.

13.3.8.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 13.26. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).	String
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .

Parameter	Description	Values
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).	String
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	 IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	<p>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</p> 	<p>Mint, Passthrough, Manual, or an empty string ("").</p>
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	<p>false or true</p>

Parameter	Description	Values
imageContentSources	Sources and repositories for the release-image content.	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.	Internal or External . The default value is External . Setting this field to Internal is not supported on non-cloud platforms.
sshKey	The SSH key or keys to authenticate access your cluster machines.  NOTE For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.	One or more keys. For example: sshKey: <key1> <key2> <key3>

13.3.8.2. Sample `install-config.yaml` file for IBM Z

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```
apiVersion: v1
baseDomain: example.com 1
compute: 2
- hyperthreading: Enabled 3
  name: worker
replicas: 0 4
  architecture : s390x
controlPlane: 5
    hyperthreading: Enabled 6
```

- 1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.
 - 2 5 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.
 - 3 6 Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not available on your OpenShift Container Platform nodes, the **hyperthreading** parameter has no effect.

IMPORTANT

If you disable **hyperthreading**, whether on your OpenShift Container Platform nodes or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

- 4 You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

- 7 The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.
- 8 The cluster name that you specified in your DNS records.
- 9 A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.
- 10 The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to **23**, then each node is assigned a /23 subnet out of the given **cidr**, which allows for 510 ($2^{32} - 23$) - 2 pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.
- 11 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.
- 12 You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Z infrastructure.

WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as [installing a cluster on any platform](#), and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.
2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

13

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

14

For **<local_registry>**, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, **registry.example.com** or **registry.example.com:5000**. For **<credentials>**, specify the base64-encoded user name and password for your mirror registry.

15

The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

16

Add the **additionalTrustBundle** parameter and value. The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

17

Provide the **imageContentSources** section from the output of the command to mirror the repository.

13.3.8.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

- If your cluster is on AWS, you added the **ec2.<region>.amazonaws.com**, **elasticloadbalancing.<region>.amazonaws.com**, and **s3.<region>.amazonaws.com** endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

- 1 Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ①
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
  noProxy: example.com ③
  additionalTrustBundle: | ④
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
  ...
  ...
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpProxy** value.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpsProxy** value.

- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace to hold the additional CA certificates. If you provide **additionalTrustBundle** and at least one proxy setting, the **Proxy** object is configured to reference the **user-ca-bundle** config map in the **trustedCA** field. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges the contents specified for the **trustedCA** parameter with the RHCOS trust bundle. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE

The installation program does not support the proxy **readinessEndpoints** field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

13.3.8.4. Configuring a three-node cluster

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing **install-config.yaml** file.

Procedure

- Ensure that the number of compute replicas is set to **0** in your **install-config.yaml** file, as shown in the following **compute** stanza:

```
compute:
- name: worker
  platform: {}
  replicas: 0
```

NOTE

You must set the value of the **replicas** parameter for the compute machines to **0** when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

NOTE

The preferred resource for control plane nodes is six vCPUs and 21 GB. For three control plane nodes this is the memory + vCPU equivalent of a minimum five-node cluster. You should back the three nodes, each installed on a 120 GB disk, with three IFLs that are SMT2 enabled. The minimum tested setup is three vCPUs and 10 GB on a 120 GB disk for each control plane node.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.
- When you create the Kubernetes manifest files in the following procedure, ensure that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file is set to **true**. This enables your application workloads to run on the control plane nodes.
- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

13.3.9. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named **cluster**. The CR specifies the fields for the **Network** API in the **operator.openshift.io** API group.

The CNO configuration inherits the following fields during cluster installation from the **Network** API in the **Network.config.openshift.io** API group and these fields cannot be changed:

clusterNetwork

IP address pools from which pod IP addresses are allocated.

serviceNetwork

IP address pool for services.

defaultNetwork.type

Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

13.3.9.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

Table 13.27. Cluster Network Operator configuration object

Field	Type	Description
metadata.name	string	The name of the CNO object. This name is always cluster .
spec.clusterNetwork	array	<p>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</p> <pre>spec: clusterNetwork: - cidr: 10.128.0.0/19 hostPrefix: 23 - cidr: 10.128.32.0/19 hostPrefix: 23</pre> <p>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</p>
spec.serviceNetwork	array	<p>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:</p> <pre>spec: serviceNetwork: - 172.30.0.0/14</pre> <p>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</p>
spec.defaultNetwork	object	Configures the Container Network Interface (CNI) cluster network provider for the cluster network.
spec.kubeProxyConfig	object	The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

defaultNetwork object configuration

The values for the **defaultNetwork** object are defined in the following table:

Table 13.28. defaultNetwork object

Field	Type	Description
type	string	<p>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</p>  <p>NOTE</p> <p>OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.</p>
openshiftSDNConfig	object	This object is only valid for the OpenShift SDN cluster network provider.
ovnKubernetesConfig	object	This object is only valid for the OVN-Kubernetes cluster network provider.

Configuration for the OpenShift SDN CNI cluster network provider

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

Table 13.29. **openshiftSDNConfig** object

Field	Type	Description
mode	string	<p>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy.</p> <p>The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</p>

Field	Type	Description
mtu	integer	<p>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.</p> <p>This value cannot be changed after cluster installation.</p>
vxlanPort	integer	<p>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.</p> <p>If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.</p> <p>On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</p>

Example OpenShift SDN configuration

```
defaultNetwork:
type: OpenShiftSDN
openshiftSDNConfig:
  mode: NetworkPolicy
  mtu: 1450
  vxlanPort: 4789
```

Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

Table 13.30. ovnKubernetesConfig object

Field	Type	Description
-------	------	-------------

Field	Type	Description
mtu	integer	<p>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.</p> <p>This value cannot be changed after cluster installation.</p>
genevePort	integer	The port to use for all Geneve packets. The default value is 6081 . This value cannot be changed after cluster installation.
policyAuditConfig	object	Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.

Table 13.31. **policyAuditConfig** object

Field	Type	Description
rateLimit	integer	The maximum number of messages to generate every second per node. The default value is 20 messages per second.
maxFileSize	integer	The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.

Field	Type	Description
destination	string	<p>One of the following additional audit log targets:</p> <ul style="list-style-type: none"> libc The libc syslog() function of the journald process on the host. udp:<host>:<port> A syslog server. Replace <host>:<port> with the host and port of the syslog server. unix:<file> A Unix Domain Socket file specified by <file>. null Do not send the audit logs to any additional target.
syslogFacility	string	The syslog facility, such as kern , as defined by RFC5424. The default value is local0 .

Example OVN-Kubernetes configuration

```
defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
```

kubeProxyConfig object configuration

The values for the **kubeProxyConfig** object are defined in the following table:

Table 13.32. **kubeProxyConfig** object

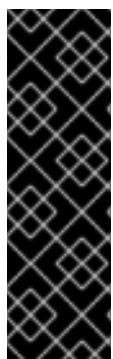

Field	Type	Description
iptablesSyncPeriod	string	<p>The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</p> <div style="text-align: right; margin-top: 20px;">  NOTE Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary. </div>

Field	Type	Description
proxyArguments.iptables-min-sync-period	array	<p>The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s, m, and h and are described in the Go time package. The default value is:</p> <pre>kubeProxyConfig: proxyArguments: iptables-min-sync-period: - 0s</pre>

13.3.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the [client image mirror](#). The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the **install-config.yaml** installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

Example output

```
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift
```

- For <installation_directory>, specify the installation directory that contains the **install-config.yaml** file you created.

WARNING

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

- Check that the **mastersSchedulable** parameter in the <installation_directory>/manifests/cluster-scheduler-02-config.yml Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
 - Open the <installation_directory>/manifests/cluster-scheduler-02-config.yml file.
 - Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
 - Save and exit the file.
- To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory> ①
```

- For <installation_directory>, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the <installation_directory>/auth directory:

13.3.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Z infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) as Red Hat Enterprise Linux (RHEL) guest virtual machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

You can perform a fast-track installation of RHCOS that uses a prepackaged QEMU copy-on-write (QCOW2) disk image. Alternatively, you can perform a full installation on a new QCOW2 disk image.

13.3.11.1. Fast-track installation by using a prepackaged QCOW2 disk image

Complete the following steps to create the machines in a fast-track installation of Red Hat Enterprise Linux CoreOS (RHCOS), importing a prepackaged Red Hat Enterprise Linux CoreOS (RHCOS) QEMU copy-on-write (QCOW2) disk image.

Prerequisites

- At least 1 LPAR running RHEL 8.3 with KVM, referred to as RHEL KVM host in this procedure.
- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
- A DHCP server that provides IP addresses.

Procedure

1. Obtain the RHEL QEMU copy-on-write (QCOW2) disk image file from the [Product Downloads](#) page on the Red Hat Customer Portal or from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

2. Download the QCOW2 disk image and Ignition files to a common directory on the RHEL KVM host.

For example: `/var/lib/libvirt/images`

NOTE

The Ignition files are generated by the OpenShift Container Platform installer.

3. Create a new disk image with the QCOW2 disk image backing file for each KVM guest node.

```
$ qemu-img create -f qcow2 -F qcow2 -b /var/lib/libvirt/images/{source_rhcos_qemu}
/var/lib/libvirt/images/{vmname}.qcow2 {size}
```

4. Create the new KVM guest nodes using the Ignition file and the new disk image.

```
$ virt-install --noautoconsole \
--connect qemu:///system \
--name {vn_name} \
--memory {memory} \
--vcpus {vcpus} \
--disk {disk} \
--import \
--network network={network},mac={mac} \
--qemu-commandline="-drive \
if=none,id=ignition,format=raw,file={ign_file},readonly=on -device virtio-
blk,serial=ignition,drive=ignition"
```

13.3.11.2. Full installation on a new QCOW2 disk image

Complete the following steps to create the machines in a full installation on a new QEMU copy-on-write (QCOW2) disk image.

Prerequisites

- At least 1 LPAR running RHEL 8.3 with KVM, referred to as RHEL KVM host in this procedure.
- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
- An HTTP or HTTPS server is set up.

Procedure

1. Obtain the RHEL kernel, initramfs, and rootfs files from the [Product Downloads](#) page on the Red Hat Customer Portal or from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- kernel: **rhcoss-<version>-live-kernel-<architecture>**
 - initramfs: **rhcoss-<version>-live-initramfs.<architecture>.img**
 - rootfs: **rhcoss-<version>-live-rootfs.<architecture>.img**
2. Move the downloaded RHEL live kernel, initramfs, and rootfs as well as the Ignition files to an HTTP or HTTPS server before you launch **virt-install**.

**NOTE**

The Ignition files are generated by the OpenShift Container Platform installer.

3. Create the new KVM guest nodes using the RHEL kernel, initramfs, and Ignition files, the new disk image, and adjusted parm line arguments.
 - For **--location**, specify the location of the kernel/initrd on the HTTP or HTTPS server.
 - For **coreos.inst.ignition_url=**, specify the Ignition file for the machine role. Use **bootstrap.ign**, **master.ign**, or **worker.ign**. Only HTTP and HTTPS protocols are supported.
 - For **coreos.live.rootfs_url=**, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

```
$ virt-install \
--connect qemu:///system \
--name {vn_name} \
--vcpus {vcpus} \
--memory {memory_mb} \
--disk {vn_name}.qcow2,size={image_size} default(10,true) \
--network network={virt_network_parm} \
--boot hd \
--location {media_location},kernel={rhcos_kernel},initrd={rhcos_initrd} \
--extra-args "rd.neednet=1 coreos.inst=yes coreos.inst.install_dev=vda
coreos.live.rootfs_url={rhcos_liveos} ip={ip}:{default_gateway}:{subnet_mask_length}:
{vn_name}:enc1:none:{MTU} nameserver={dns} coreos.inst.ignition_url={rhcos_ign}" \
--noautoconsole \
--wait
```

13.3.11.3. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the **coreos-installer** command.

13.3.11.3.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

**IMPORTANT**

When adding networking arguments manually, you must also add the **rd.neednet=1** kernel argument to bring the network up in the initramfs.

The following table provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the **ip=**, **nameserver=**, and **bond=** kernel arguments.

NOTE

Ordering is important when adding the kernel arguments: **ip=**, **nameserver=**, and then **bond=**.

The networking options are passed to the **dracut** tool during system boot. For more information about the networking options supported by **dracut**, see the **dracut.cmdline** manual page.

Table 13.33. Networking and bonding options for ISO installations

Description	Examples
<p>To configure an IP address, either use DHCP (ip=dhcp) or set an individual static IP address (ip=<host_ip>). If setting a static IP, you must then identify the DNS server IP address (nameserver=<dns_ip>) on each node. This example sets:</p> <ul style="list-style-type: none"> • The node's IP address to 10.10.10.2 • The gateway address to 10.10.10.254 • The netmask to 255.255.255.0 • The hostname to core0.example.com • The DNS server address to 4.4.4.41 • The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically. 	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp1s0:none nameserver=4.4.4.41</pre>
<p> NOTE</p> <p>When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.</p>	
<p>Specify multiple network interfaces by specifying multiple ip= entries.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp1s0:none ip=10.10.10.3::10.10.10.254:255.255.255.0:co re0.example.com:enp2s0:none</pre>

Description	Examples
<p>Optional: You can configure routes to additional networks by setting an rd.route= value.</p> <p>If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.</p>	<p>To configure the default gateway:</p> <pre>ip:::10.10.10.254:::</pre> <p>To configure the route for the additional network:</p> <pre>rd.route=20.20.20.0/24:20.20.20.254:enp2s0</pre>
<p>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the enp1s0 interface has a static networking configuration and DHCP is disabled for enp2s0, which is not used.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp1s0:none ip::::core0.example.com:enp2s0:none</pre>
<p>You can combine DHCP and static IP configurations on systems with multiple network interfaces.</p>	<pre>ip=enp1s0:dhcp ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp2s0:none</pre>
<p>Optional: You can configure VLANs on individual interfaces by using the vlan= parameter.</p>	<p>To configure a VLAN on a network interface and use a static IP address:</p> <pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp2s0.100:none vlan=enp2s0.100:enp2s0</pre> <p>To configure a VLAN on a network interface and to use DHCP:</p> <pre>ip=enp2s0.100:dhcp vlan=enp2s0.100:enp2s0</pre>
<p>You can provide multiple DNS servers by adding a nameserver= entry for each server.</p>	<pre>nameserver=1.1.1.1 nameserver=8.8.8.8</pre>

Description	Examples
<p>Optional: Bonding multiple network interfaces to a single interface is supported using the bond= option. In these two examples:</p> <ul style="list-style-type: none"> The syntax for configuring a bonded interface is: bond=name[:network_interfaces][:options] <i>name</i> is the bonding device name (bond0), <i>network_interfaces</i> represents a comma-separated list of physical (ethernet) interfaces (em1,em2), and <i>options</i> is a comma-separated list of bonding options. Enter modinfo bonding to see available options. When you create a bonded interface using bond=, you must specify how the IP address is assigned and other information for the bonded interface. 	<p>To configure the bonded interface to use DHCP, set the bond's IP address to dhcp. For example:</p> <pre>bond=bond0:em1,em2:mode=active-backup ip=bond0:dhcp</pre> <p>To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:</p> <pre>bond=bond0:em1,em2:mode=active-backup ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:bond0:none</pre>
<p>Optional: You can configure VLANs on bonded interfaces by using the vlan= parameter.</p>	<p>To configure the bonded interface with a VLAN and to use DHCP:</p> <pre>ip=bond0.100:dhcp bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0</pre> <p>To configure the bonded interface with a VLAN and to use a static IP address:</p> <pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:bond0.100:none bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0</pre>

13.3.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.

- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

```
$ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \ ①
--log-level=info ②
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.22.1 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

IMPORTANT

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

13.3.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- 1** For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

13.3.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.22.1
master-1	Ready	master	63m	v1.22.1
master-2	Ready	master	64m	v1.22.1

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-8b2br	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending

```
csr-8vnps 15m system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending
```

...

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

①

<csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	Pending
csr-c57lv	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	Pending
...			

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	73m	v1.22.1
master-1	Ready	master	73m	v1.22.1
master-2	Ready	master	74m	v1.22.1
worker-0	Ready	worker	11m	v1.22.1
worker-1	Ready	worker	11m	v1.22.1

NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

13.3.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.9.0	True	False	False 19m
baremetal	4.9.0	True	False	False 37m
cloud-credential	4.9.0	True	False	False 40m
cluster-autoscaler	4.9.0	True	False	False 37m
config-operator	4.9.0	True	False	False 38m
console	4.9.0	True	False	False 26m
csi-snapshot-controller	4.9.0	True	False	False 37m
dns	4.9.0	True	False	False 37m
etcd	4.9.0	True	False	False 36m
image-registry	4.9.0	True	False	False 31m
ingress	4.9.0	True	False	False 30m
insights	4.9.0	True	False	False 31m
kube-apiserver	4.9.0	True	False	False 26m
kube-controller-manager	4.9.0	True	False	False 36m
kube-scheduler	4.9.0	True	False	False 36m
kube-storage-version-migrator	4.9.0	True	False	False 37m
machine-api	4.9.0	True	False	False 29m
machine approver	4.9.0	True	False	False 37m
machine-config	4.9.0	True	False	False 36m
marketplace	4.9.0	True	False	False 37m
monitoring	4.9.0	True	False	False 29m
network	4.9.0	True	False	False 38m
node-tuning	4.9.0	True	False	False 37m
openshift-apiserver	4.9.0	True	False	False 32m
openshift-controller-manager	4.9.0	True	False	False 30m
openshift-samples	4.9.0	True	False	False 32m
operator-lifecycle-manager	4.9.0	True	False	False 37m
operator-lifecycle-manager-catalog	4.9.0	True	False	False 37m
operator-lifecycle-manager-packageserver	4.9.0	True	False	False 32m
service-ca	4.9.0	True	False	False 38m
storage	4.9.0	True	False	False 37m

2. Configure the Operators that are not available.

13.3.15.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding **disableAllDefaultSources: true** to the **OperatorHub** object:

```
$ oc patch OperatorHub cluster --type json \
-p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
```

TIP

Alternatively, you can use the web console to manage catalog sources. From the **Administration → Cluster Settings → Global Configuration → OperatorHub** page, click the **Sources** tab, where you can create, delete, disable, and enable individual sources.

13.3.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

13.3.15.2.1. Configuring registry storage for bare metal and other manual installations

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster that uses manually-provisioned Red Hat Enterprise Linux CoreOS (RHCOS) nodes, such as bare metal.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Container Storage.

IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

Procedure

- To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

NOTE

When using shared storage, review your security settings to prevent outside access.

- Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry
```

NOTE

If the storage type is **emptyDIR**, the replica number cannot be greater than **1**.

- Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

Example output

```
storage:
  pvc:
    claim:
```

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

- Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

- Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

```
$ oc edit configs.imageregistry/cluster
```

Then, change the line

```
managementState: Removed
```

to

```
managementState: Managed
```

13.3.15.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage":{"emptyDir":{}}}}'
```

WARNING

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

13.3.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

- Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME	VERSION	AVAILABLE	PROGRESSING	DEGRADED
SINCE				
authentication	4.9.0	True	False	False 19m
baremetal	4.9.0	True	False	False 37m
cloud-credential	4.9.0	True	False	False 40m
cluster-autoscaler	4.9.0	True	False	False 37m
config-operator	4.9.0	True	False	False 38m
console	4.9.0	True	False	False 26m

csi-snapshot-controller	4.9.0	True	False	False	37m
dns	4.9.0	True	False	False	37m
etcd	4.9.0	True	False	False	36m
image-registry	4.9.0	True	False	False	31m
ingress	4.9.0	True	False	False	30m
insights	4.9.0	True	False	False	31m
kube-apiserver	4.9.0	True	False	False	26m
kube-controller-manager	4.9.0	True	False	False	36m
kube-scheduler	4.9.0	True	False	False	36m
kube-storage-version-migrator	4.9.0	True	False	False	37m
machine-api	4.9.0	True	False	False	29m
machine approver	4.9.0	True	False	False	37m
machine-config	4.9.0	True	False	False	36m
marketplace	4.9.0	True	False	False	37m
monitoring	4.9.0	True	False	False	29m
network	4.9.0	True	False	False	38m
node-tuning	4.9.0	True	False	False	37m
openshift-apiserver	4.9.0	True	False	False	32m
openshift-controller-manager	4.9.0	True	False	False	30m
openshift-samples	4.9.0	True	False	False	32m
operator-lifecycle-manager	4.9.0	True	False	False	37m
operator-lifecycle-manager-catalog	4.9.0	True	False	False	37m
operator-lifecycle-manager-packageserver	4.9.0	True	False	False	32m
service-ca	4.9.0	True	False	False	38m
storage	4.9.0	True	False	False	37m

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete ①
```

- ① For <installation_directory>, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.

- To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

Example output

NAMESPACE	NAME	READY	STATUS
RESTARTS	AGE		
openshift-apiserver-operator	openshift-apiserver-operator-85cb746d55-zqhs8	1/1	
Running 1 9m			
openshift-apiserver	apiserver-67b9g	1/1	Running 0
3m			
openshift-apiserver	apiserver-ljcmx	1/1	Running 0
1m			
openshift-apiserver	apiserver-z25h4	1/1	Running 0
2m			
openshift-authentication-operator	authentication-operator-69d5d8bf84-vh2n8	1/1	
Running 0 5m			
...			

- View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> ①
```

- ① Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

- For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.
See "Enabling multipathing with kernel arguments on RHCOS" in the *Post-installation machine configuration tasks* documentation for more information.
- Register your cluster on the [Cluster registration](#) page.

13.3.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

13.3.18. Collecting debugging information

You can gather debugging information that might help you to troubleshoot and debug certain issues with an OpenShift Container Platform installation on IBM Z.

Prerequisites

- The **oc** CLI tool installed.

Procedure

1. Log in to the cluster:

```
$ oc login -u <username>
```

2. On the node you want to gather hardware information about, start a debugging container:

```
$ oc debug node/<nodename>
```

3. Change to the **/host** file system and start **toolbox**:

```
$ chroot /host  
$ toolbox
```

4. Collect the **dbginfo** data:

```
$ dbginfo.sh
```

5. You can then retrieve the data, for example, using **scp**.

Additional resources

- [How to generate SOSREPORT within OpenShift Container Platform version 4 nodes without SSH.](#)

13.3.19. Next steps

- [Customize your cluster.](#)
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by [configuring additional trust stores](#).

CHAPTER 14. INSTALLING ON IBM POWER SYSTEMS

14.1. PREPARING TO INSTALL ON IBM POWER SYSTEMS

14.1.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).

14.1.2. Choosing a method to install OpenShift Container Platform on IBM Power Systems

You can install a cluster on IBM Power Systems infrastructure that you provision, by using one of the following methods:

- **[Installing a cluster on IBM Power Systems](#)** You can install OpenShift Container Platform on IBM Power Systems infrastructure that you provision.
- **[Installing a cluster on IBM Power Systems in a restricted network](#)** You can install OpenShift Container Platform on IBM Power Systems infrastructure that you provision in a restricted or disconnected network, by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

14.2. INSTALLING A CLUSTER ON IBM POWER SYSTEMS

In OpenShift Container Platform version 4.9, you can install a cluster on IBM Power Systems infrastructure that you provision.

IMPORTANT

Additional considerations exist for non-bare metal platforms. Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you install an OpenShift Container Platform cluster.

14.2.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- Before you begin the installation process, you must clean the installation directory. This ensures that the required installation files are created and updated during the installation process.
- You provisioned [persistent storage using NFS](#) for your cluster. To deploy a private image registry, your storage must provide **ReadWriteMany** access modes.

- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

NOTE

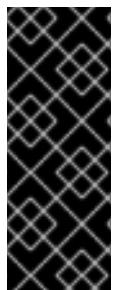

Be sure to also review this site list if you are configuring a proxy.

14.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

14.2.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

14.2.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

Table 14.1. Minimum required hosts

Hosts	Description
One temporary bootstrap machine	The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.
Three control plane machines	The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.

Hosts	Description
At least two compute machines, which are also known as worker machines.	The workloads requested by OpenShift Container Platform users run on the compute machines.

IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 7.9, or RHEL 8.4.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

14.2.3.2. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

Machine	Operating System	vCPU [1]	Virtual RAM	Storage	IOPS [2]
Bootstrap	RHCOS	2	16 GB	100 GB	300
Control plane	RHCOS	2	16 GB	100 GB	300
Compute	RHCOS	2	8 GB	100 GB	300

- One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
- OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
- As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

14.2.3.3. Minimum IBM Power Systems requirements

You can install OpenShift Container Platform version 4.9 on the following IBM hardware:

- IBM POWER8 or POWER9 processor-based systems

Hardware requirements

- 6 IBM Power bare metal servers or 6 LPARs across multiple PowerVM servers

Operating system requirements

- One instance of an IBM POWER8 or POWER9 processor-based system

On your IBM Power instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

Disk storage for the IBM Power guest virtual machines

- Storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

Network for the PowerVM guest virtual machines

- Virtualized by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM vNIC

Storage / main memory

- 100 GB / 16 GB for OpenShift Container Platform control plane machines
- 100 GB / 8 GB for OpenShift Container Platform compute machines
- 100 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

14.2.3.4. Recommended IBM Power system requirements**Hardware requirements**

- 6 IBM Power bare metal servers or 6 LPARs across multiple PowerVM servers

Operating system requirements

- One instance of an IBM POWER8 or POWER9 processor-based system

On your IBM Power instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

Disk storage for the IBM Power guest virtual machines

- Storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

Network for the PowerVM guest virtual machines

- Virtualized by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM vNIC

Storage / main memory

- 120 GB / 32 GB for OpenShift Container Platform control plane machines
- 120 GB / 32 GB for OpenShift Container Platform compute machines
- 120 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

14.2.3.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

14.2.3.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.

NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

14.2.3.6.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through

NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

14.2.3.6.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 14.2. Ports used for all-machine to all-machine communications

Protocol	Port	Description
ICMP	N/A	Network reachability tests
TCP	1936	Metrics
	9000-9999	Host level services, including the node exporter on ports 9100-9101 and the Cluster Version Operator on port 9099 .
	10250-10259	The default ports that Kubernetes reserves
	10256	openshift-sdn
UDP	4789	VXLAN and Geneve
	6081	VXLAN and Geneve
	9000-9999	Host level services, including the node exporter on ports 9100-9101 .
TCP/UDP	30000-32767	Kubernetes node port

Table 14.3. Ports used for all-machine to control plane communications

Protocol	Port	Description
TCP	6443	Kubernetes API

Table 14.4. Ports used for control plane machine to control plane machine communications

Protocol	Port	Description
TCP	2379-2380	etcd server and peer ports

NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

Additional resources

- [Configuring chrony time service](#)

14.2.3.7. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

**NOTE**

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the *DHCP recommendations for user-provisioned infrastructure* section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, **<cluster_name>** is the cluster name and **<base_domain>** is the base domain that you specify in the **install-config.yaml** file. A complete DNS

record takes the form: <component>.<cluster_name>.<base_domain>..

Table 14.5. Required DNS records

Component	Record	Description
Kubernetes API	api.<cluster_name>.<base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.
	api-int.<cluster_name>.<base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.
		 IMPORTANT The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
Routes	*.apps.<cluster_name>.<base_domain>.	A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.<cluster_name>.<base_domain> is used as a wildcard route to the OpenShift Container Platform console.
Bootstrap machine	bootstrap.<cluster_name>.<base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.
Control plane machines	<master><n>.<cluster_name>.<base_domain>.	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.
Compute machines	<worker><n>.<cluster_name>.<base_domain>.	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

TIP

You can use the **dig** command to verify name and reverse name resolution. See the section on [Validating DNS resolution for user-provisioned infrastructure](#) for detailed validation steps.

14.2.3.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is **ocp4** and the base domain is **example.com**.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

Example 14.1. Sample DNS zone database

```
$TTL 1W
@ IN SOA ns1.example.com. root (
    2019070700 ; serial
    3H ; refresh (3 hours)
    30M ; retry (30 minutes)
    2W ; expiry (2 weeks)
    1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.

;
;

ns1.example.com. IN A 192.168.1.5
smtp.example.com. IN A 192.168.1.5
;
helper.example.com. IN A 192.168.1.5
helper.ocp4.example.com. IN A 192.168.1.5

api-int.ocp4.example.com. IN A 192.168.1.5 ②
;
*.apps.ocp4.example.com. IN A 192.168.1.5 ③
;
bootstrap.ocp4.example.com. IN A 192.168.1.96 ④
;
master0.ocp4.example.com. IN A 192.168.1.97 ⑤
master1.ocp4.example.com. IN A 192.168.1.98 ⑥
master2.ocp4.example.com. IN A 192.168.1.99 ⑦
;
worker0.ocp4.example.com. IN A 192.168.1.11 ⑧
```

```
worker1.ocp4.example.com. IN A 192.168.1.7 9
;
;EOF
```

- 1 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.
- 2 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.
- 3 Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

- 4 Provides name resolution for the bootstrap machine.
- 5 6 7 Provides name resolution for the control plane machines.
- 8 9 Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 14.2. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root (
    2019070700 ; serial
    3H ; refresh (3 hours)
    30M ; retry (30 minutes)
    2W ; expiry (2 weeks)
    1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6
```

```

;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
;
:EOF

```

- 1 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
- 2 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
- 3 Provides reverse DNS resolution for the bootstrap machine.
- 4 5 6 Provides reverse DNS resolution for the control plane machines.
- 7 8 Provides reverse DNS resolution for the compute machines.

NOTE

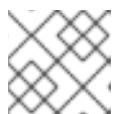

A PTR record is not required for the OpenShift Container Platform application wildcard.

14.2.3.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer.** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
 - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
 - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

NOTE

Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

Table 14.6. API load balancer

Port	Back-end machines (pool members)	Internal	External	Description
------	----------------------------------	----------	----------	-------------

Port	Back-end machines (pool members)	Internal	External	Description
6443	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.	X	X	Kubernetes API server
22623	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.	X		Machine config server

NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the **/readyz** endpoint to the removal of the API server instance from the pool. Within the time frame after **/readyz** returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer:** Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 14.7. Application ingress load balancer

Port	Back-end machines (pool members)	Internal	External	Description
443	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTPS traffic

Port	Back-end machines (pool members)	Internal	External	Description
80	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTP traffic

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

14.2.3.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an **/etc/haproxy/haproxy.cfg** configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 14.3. Sample API and application ingress load balancer configuration

```

global
  log    127.0.0.1 local2
  pidfile /var/run/haproxy.pid
  maxconn 4000
  daemon
defaults
  mode      http
  log       global
  option    dontlognull
  option http-server-close
  option    redispatch
  retries   3
  timeout http-request 10s
  timeout queue     1m
  timeout connect   10s
  timeout client    1m
  timeout server    1m
  timeout http-keep-alive 10s

```

```

timeout check      10s
maxconn          3000
frontend stats
  bind *:1936
    mode      http
    log       global
    maxconn 10
  stats enable
  stats hide-version
  stats refresh 30s
  stats show-node
  stats show-desc Stats for ocp4 cluster 1
  stats auth admin:ocp4
  stats uri /stats
listen api-server-6443 2
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup 3
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623 4
  bind *:22623
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup 5
  server master0 master0.ocp4.example.com:22623 check inter 1s
  server master1 master1.ocp4.example.com:22623 check inter 1s
  server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443 6
  bind *:443
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:443 check inter 1s
  server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80 7
  bind *:80
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:80 check inter 1s
  server worker1 worker1.ocp4.example.com:80 check inter 1s

```

- 1** In the example, the cluster name is **ocp4**.
- 2** Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
- 3** **5** The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.
- 4** Port **22623** handles the machine config server traffic and points to the control plane machines.
- 6** Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
- 7** Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

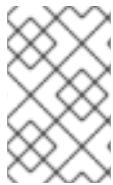

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltpu** on the HAProxy node.

NOTE

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy_connect_any=1**.

14.2.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

Prerequisites

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
 - a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
 - b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

NOTE

If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap* process section for more information about static IP provisioning and advanced networking options.

- c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the *Setting the cluster node hostnames through DHCP* section for details about hostname considerations.

NOTE

If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.
3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.
4. Setup the required DNS infrastructure for your cluster.
 - a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
 - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.
5. Validate your DNS configuration.
 - a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
 - b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.

See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.
6. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

14.2.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
 - a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> ①
```

- ① Replace **<nameserver_ip>** with the IP address of the nameserver, **<cluster_name>** with your cluster name, and **<base_domain>** with your base domain name.

Example output

```
api.ocp4.example.com. 0 IN A 192.168.1.5
```

- b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

```
api-int.ocp4.example.com. 0 IN A 192.168.1.5
```

- c. Test an example ***.apps.<cluster_name>.<base_domain>** DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

random.apps.ocp4.example.com. 0 IN A 192.168.1.5

NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace **random** with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5

- d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

bootstrap.ocp4.example.com. 0 IN A 192.168.1.96

- e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.
 - a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. ①  
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. ②
```

- ① Provides the record name for the Kubernetes internal API.
- ② Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

- b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

- c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

14.2.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> ①
```

- Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

- View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

- Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

- Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name>
```

1

- Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

14.2.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

- Access the [Infrastructure Provider](#) page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
- Select your infrastructure provider.
- Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

- Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

- From the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

14.2.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.9. Download and install the new version of **oc**.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.9 Linux Client** entry and save the file.
4. Unpack the archive:

```
$ tar xvzf <file>
```

5. Place the **oc** binary in a directory that is on your **PATH**.

To check your **PATH**, execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.9 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.9 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

14.2.9. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

- Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation_directory>**.

**NOTE**

You must name this configuration file **install-config.yaml**.

**NOTE**

For some platform types, you can alternatively run `./openshift-install create install-config --dir=<installation_directory>` to generate an **install-config.yaml** file. You can provide details about your cluster configuration at the prompts.

- Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

14.2.9.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized **install-config.yaml** installation configuration file that describes the details for your environment.

**NOTE**

After installation, you cannot modify these parameters in the **install-config.yaml** file.

**IMPORTANT**

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

14.2.9.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 14.8. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String

Parameter	Description	Values
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>. <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}} .	String of lowercase letters, hyphens (-), and periods (.), such as dev .
platform	The configuration for the specific platform upon which to perform the installation: aws , baremetal , azure , openstack , ovirt , vsphere , or {} . For additional information about platform . <platform> parameters, consult the table for your specific platform that follows.	Object
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths":{ "cloud.openshift.com":{ "auth":"b3Blb=", "email":"you@example.com" }, "quay.io":{ "auth":"b3Blb=", "email":"you@example.com" } } }</pre>

14.2.9.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 14.9. Network parameters

Parameter	Description	Values
networking	The configuration for the cluster network.	<p>Object</p>  <p>NOTE</p> <p>You cannot modify parameters specified by the networking object after installation.</p>
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	<p>The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>	<p>An array of objects. For example:</p> <pre>networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</pre>
networking.clusterNetwork.cidr	<p>Required if you use networking.clusterNetwork. An IP address block.</p> <p>An IPv4 network.</p>	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{32-23}-2$) pod IP addresses.	<p>A subnet prefix.</p> <p>The default value is 23.</p>

Parameter	Description	Values
networking.serviceNetwork	<p>The IP address block for services. The default value is 172.30.0.0/16.</p> <p>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</p>	An array with an IP address block in CIDR format. For example: <pre>networking: serviceNetwork: - 172.30.0.0/16</pre>
networking.machineNetwork	<p>The IP address blocks for machines.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p> <p>If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.</p>	An array of objects. For example: <pre>networking: machineNetwork: - cidr: 10.0.0.0/16</pre>
networking.machineNetwork.cidr	<p>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</p>	<p>An IP network block in CIDR notation.</p> <p>For example, 10.0.0.0/16.</p>  <p>NOTE Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.</p>

14.2.9.1.3. Optional configuration parameters

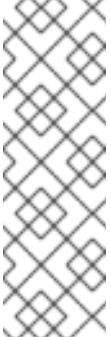

Optional installation configuration parameters are described in the following table:

Table 14.10. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.

Parameter	Description	Values
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are ppc64le (the default).	String
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p>IMPORTANT</p>  <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere , or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.

Parameter	Description	Values
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are ppc64le (the default).	String
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws , azure , gcp , openstack , ovirt , vsphere , or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.	Mint, Passthrough, Manual , or an empty string ("").
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>NOTE</p> <p>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the <i>Cloud Credential Operator</i> entry in the <i>Red Hat Operators</i> reference content.</p>	false or true
imageContentSources	 <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.

Parameter	Description	Values
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.	Internal or External . The default value is External . Setting this field to Internal is not supported on non-cloud platforms.
sshKey	The SSH key or keys to authenticate access your cluster machines. 	One or more keys. For example: sshKey: <key1> <key2> <key3>

14.2.9.2. Sample `install-config.yaml` file for IBM Power Systems

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```

apiVersion: v1
baseDomain: example.com ①
compute: ②
- hyperthreading: Enabled ③
  name: worker
  replicas: 0 ④
  architecture : ppc64le
controlPlane: ⑤
  hyperthreading: Enabled ⑥
  name: master
  replicas: 3 ⑦
  architecture : ppc64le
metadata:
  name: test ⑧
networking:
```

```

clusterNetwork:
- cidr: 10.128.0.0/14 9
  hostPrefix: 23 10
networkType: OpenShiftSDN
serviceNetwork: 11
- 172.30.0.0/16
platform:
  none: {} 12
fips: false 13
pullSecret: '{"auths": ...}' 14
sshKey: 'ssh-ed25519 AAAA...' 15

```

1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2 **5** The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, **-**, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

3 **6** Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

IMPORTANT

If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

4 You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

7 The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

8 The cluster name that you specified in your DNS records.

- 9 A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to
- 10 The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to **23**, then each node is assigned a /23 subnet out of the given **cidr**, which allows for 510 ($2^{(32 - 23)} - 2$) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.
- 11 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.
- 12 You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Power Systems infrastructure.

WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as [installing a cluster on any platform](#), and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.
2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

- 13 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

- 14 The pull secret that you obtained from the [Red Hat OpenShift Cluster Manager](#) site. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.
- 15 The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

14.2.9.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

- If your cluster is on AWS, you added the **ec2.<region>.amazonaws.com**, **elasticloadbalancing.<region>.amazonaws.com**, and **s3.<region>.amazonaws.com** endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ①
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
  noProxy: example.com ③
  additionalTrustBundle: | ④
    -----BEGIN CERTIFICATE-----
```

```
<MY_TRUSTED_CA_CERT>
-----END CERTIFICATE-----
```

...

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpProxy** value.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpsProxy** value.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace to hold the additional CA certificates. If you provide **additionalTrustBundle** and at least one proxy setting, the **Proxy** object is configured to reference the **user-ca-bundle** config map in the **trustedCA** field. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges the contents specified for the **trustedCA** parameter with the RHCOS trust bundle. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE

The installation program does not support the proxy **readinessEndpoints** field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

14.2.9.4. Configuring a three-node cluster

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing **install-config.yaml** file.

Procedure

- Ensure that the number of compute replicas is set to **0** in your **install-config.yaml** file, as shown in the following **compute** stanza:

```
compute:
- name: worker
  platform: {}
  replicas: 0
```

NOTE

You must set the value of the **replicas** parameter for the compute machines to **0** when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.
- When you create the Kubernetes manifest files in the following procedure, ensure that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file is set to **true**. This enables your application workloads to run on the control plane nodes.
- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

14.2.10. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named **cluster**. The CR specifies the fields for the **Network** API in the **operator.openshift.io** API group.

The CNO configuration inherits the following fields during cluster installation from the **Network** API in the **Network.config.openshift.io** API group and these fields cannot be changed:

clusterNetwork

IP address pools from which pod IP addresses are allocated.

serviceNetwork

IP address pool for services.

defaultNetwork.type

Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

14.2.10.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

Table 14.11. Cluster Network Operator configuration object

Field	Type	Description
metadata.name	string	The name of the CNO object. This name is always cluster .
spec.clusterNetwork	array	<p>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</p> <pre>spec: clusterNetwork: - cidr: 10.128.0.0/19 hostPrefix: 23 - cidr: 10.128.32.0/19 hostPrefix: 23</pre> <p>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</p>
spec.serviceNetwork	array	<p>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:</p> <pre>spec: serviceNetwork: - 172.30.0.0/14</pre> <p>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</p>
spec.defaultNetwork	object	Configures the Container Network Interface (CNI) cluster network provider for the cluster network.
spec.kubeProxyConfig	object	The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

defaultNetwork object configuration

The values for the **defaultNetwork** object are defined in the following table:

Table 14.12. defaultNetwork object

Field	Type	Description
type	string	<p>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</p>  <p>NOTE</p> <p>OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.</p>
openshiftSDNConfig	object	This object is only valid for the OpenShift SDN cluster network provider.
ovnKubernetesConfig	object	This object is only valid for the OVN-Kubernetes cluster network provider.

Configuration for the OpenShift SDN CNI cluster network provider

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

Table 14.13. openshiftSDNConfig object

Field	Type	Description
mode	string	<p>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy.</p> <p>The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</p>

Field	Type	Description
mtu	integer	<p>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.</p> <p>This value cannot be changed after cluster installation.</p>
vxlanPort	integer	<p>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.</p> <p>If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.</p> <p>On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</p>

Example OpenShift SDN configuration

```

defaultNetwork:
type: OpenShiftSDN
openshiftSDNConfig:
  mode: NetworkPolicy
  mtu: 1450
  vxlanPort: 4789

```

Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

Table 14.14. ovnKubernetesConfig object

Field	Type	Description
-------	------	-------------

Field	Type	Description
mtu	integer	<p>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.</p> <p>This value cannot be changed after cluster installation.</p>
genevePort	integer	The port to use for all Geneve packets. The default value is 6081 . This value cannot be changed after cluster installation.
ipsecConfig	object	Specify an empty object to enable IPsec encryption. This value cannot be changed after cluster installation.
policyAuditConfig	object	Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.

Table 14.15. **policyAuditConfig** object

Field	Type	Description
rateLimit	integer	The maximum number of messages to generate every second per node. The default value is 20 messages per second.
maxFileSize	integer	The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.

Field	Type	Description
destination	string	<p>One of the following additional audit log targets:</p> <ul style="list-style-type: none"> libc The libc syslog() function of the journald process on the host. udp:<host>:<port> A syslog server. Replace <host>:<port> with the host and port of the syslog server. unix:<file> A Unix Domain Socket file specified by <file>. null Do not send the audit logs to any additional target.
syslogFacility	string	The syslog facility, such as kern , as defined by RFC5424. The default value is local0 .

Example OVN-Kubernetes configuration

```
defaultNetwork:
type: OVNKubernetes
ovnKubernetesConfig:
  mtu: 1400
  genevePort: 6081
  ipsecConfig: {}
```

kubeProxyConfig object configuration

The values for the **kubeProxyConfig** object are defined in the following table:

Table 14.16. **kubeProxyConfig** object

Field	Type	Description
iptablesSyncPeriod	string	<p>The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</p> <div style="text-align: right; margin-top: 20px;">  NOTE Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary. </div>

Field	Type	Description
proxyArguments.iptables-min-sync-period	array	The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s , m , and h and are described in the Go time package . The default value is: kubeProxyConfig: proxyArguments: iptables-min-sync-period: - 0s

14.2.11. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the [client image mirror](#). The Linux version of the installation program runs on ppc64le only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the **install-config.yaml** installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

Example output

```
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift
```

- For **<installation_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

WARNING

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

- Check that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
 - Open the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file.
 - Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
 - Save and exit the file.
- To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory> ①
```

- For **<installation_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation_directory>/auth** directory:

14.2.12. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Power Systems infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

Follow either the steps to use an ISO image or network PXE booting to install RHCOS on the machines.

14.2.12.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your **bootstrap.ign** Ignition config file:

```
$ sha512sum <installation_directory>/bootstrap.ign
```

Example output

```
a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf011  
6e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b  
installation_directory/bootstrap.ign
```

The digests are provided to the **coreos-installer** in a later step to validate the authenticity of the Ignition config files on the cluster nodes.

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign ①
```

Example output

```
% Total % Received % Xferd Average Speed Time Time Current
          Dload Upload Total Spent Left Speed
0 0 0 0 0 0 0 --:--:--:--:--:-- 0{"ignition": "version": "3.2.0"}, "passwd": {"users": [{"name": "core", "sshAuthorizedKeys": ["ssh-rsa..."]}}
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

- Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

rhcoss-<version>-live.<architecture>.iso

- Use the ISO to start the RHCOS installation. Use one of the following installation options:
 - Burn the ISO image to a disk and boot it directly.
 - Use ISO redirection by using a lights-out management (LOM) interface.
- Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

NOTE

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the **coreos-installer** command as outlined in the following steps, instead of adding kernel arguments.

- Run the **coreos-installer** command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device>
--ignition-hash=SHA512-<digest> ①②
```

- ① ② You must run the **coreos-installer** command by using **sudo**, because the **core** user does not have the required root privileges to perform the installation.

- 2 The **--ignition-hash** option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node.

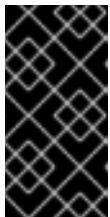

NOTE

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running **coreos-installer**.

The following example initializes a bootstrap node installation to the **/dev/sda** device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```
$ sudo coreos-installer install --ignition-
url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-
hash=SHA512-
a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf011
6e80c59d2ea9e32ba53bc807afbc581aa059311def2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.
10. Continue to create the other machines for your cluster.

IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running **ssh core@<node>.<cluster_name>**. **<base_domain>** as a user with access to the SSH private key that is paired to the public key that you specified in your **install_config.yaml** file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

14.2.12.1.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the **coreos-installer** command.

14.2.12.1.1.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

IMPORTANT

When adding networking arguments manually, you must also add the **rd.neednet=1** kernel argument to bring the network up in the initramfs.

The following table provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the **ip=**, **nameserver=**, and **bond=** kernel arguments.

NOTE

Ordering is important when adding the kernel arguments: **ip=**, **nameserver=**, and then **bond=**.

The networking options are passed to the **dracut** tool during system boot. For more information about the networking options supported by **dracut**, see the **dracut.cmdline** manual page.

Table 14.17. Networking and bonding options for ISO installations

Description	Examples
<p>To configure an IP address, either use DHCP (ip=dhcp) or set an individual static IP address (ip=<host_ip>). If setting a static IP, you must then identify the DNS server IP address (nameserver=<dns_ip>) on each node. This example sets:</p> <ul style="list-style-type: none"> ● The node's IP address to 10.10.10.2 ● The gateway address to 10.10.10.254 ● The netmask to 255.255.255.0 ● The hostname to core0.example.com ● The DNS server address to 4.4.4.41 ● The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically. <p>NOTE</p>  <p>When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none nameserver=4.4.4.41</pre>
<p>Specify multiple network interfaces by specifying multiple ip= entries.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none</pre>
<p>Optional: You can configure routes to additional networks by setting an rd.route= value.</p> <p>If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.</p>	<p>To configure the default gateway:</p> <pre>ip=:10.10.10.254:::</pre> <p>To configure the route for the additional network:</p> <pre>rd.route=20.20.20.0/24:20.20.20.254:enp2s0</pre>
<p>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the enp1s0 interface has a static networking configuration and DHCP is disabled for enp2s0, which is not used.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ip=:core0.example.com:enp2s0:none</pre>

Description	Examples
<p>You can combine DHCP and static IP configurations on systems with multiple network interfaces.</p>	<pre data-bbox="793 247 1439 370">ip=enp1s0:dhcp ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp2s0:none</pre>
<p>Optional: You can configure VLANs on individual interfaces by using the vlan= parameter.</p>	<p>To configure a VLAN on a network interface and use a static IP address:</p> <pre data-bbox="793 539 1439 662">ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp2s0.100:none vlan=enp2s0.100:enp2s0</pre> <p>To configure a VLAN on a network interface and to use DHCP:</p> <pre data-bbox="793 808 1439 932">ip=enp2s0.100:dhcp vlan=enp2s0.100:enp2s0</pre>
<p>You can provide multiple DNS servers by adding a nameserver= entry for each server.</p>	<pre data-bbox="793 1044 1439 1123">nameserver=1.1.1.1 nameserver=8.8.8.8</pre>
<p>Optional: Bonding multiple network interfaces to a single interface is supported using the bond= option. In these two examples:</p> <ul style="list-style-type: none"> • The syntax for configuring a bonded interface is: bond=name[:network_interfaces] [:options] <i>name</i> is the bonding device name (bond0), <i>network_interfaces</i> represents a comma-separated list of physical (ethernet) interfaces (em1,em2), and <i>options</i> is a comma-separated list of bonding options. Enter modinfo bonding to see available options. • When you create a bonded interface using bond=, you must specify how the IP address is assigned and other information for the bonded interface. 	<p>To configure the bonded interface to use DHCP, set the bond's IP address to dhcp. For example:</p> <pre data-bbox="793 1291 1439 1370">bond=bond0:em1,em2:mode=active-backup ip=bond0:dhcp</pre> <p>To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:</p> <pre data-bbox="793 1560 1439 1662">bond=bond0:em1,em2:mode=active-backup ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:bond0:none</pre>

Description	Examples
Optional: You can configure VLANs on bonded interfaces by using the vlan= parameter.	To configure the bonded interface with a VLAN and to use DHCP: ip=bond0.100:dhcp bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0
	To configure the bonded interface with a VLAN and to use a static IP address: ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:bond0.100:none bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0

14.2.12.2. Installing RHCOS by using PXE booting

You can use PXE booting to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign ①
```

Example output

```
% Total % Received % Xferd Average Speed Time Time Current
          Dload Upload Total Spent Left Speed
0 0 0 0 0 0 0 --:--:--:--:--:--:--:-- 0{"ignition": "version": "3.2.0"}, "passwd": {"users": [{"name": "core", "sshAuthorizedKeys": ["ssh-rsa..."]}}
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

- Obtain the RHCOS **kernel**, **initramfs** and **rootfs** files from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate **kernel**, **initramfs**, and **rootfs** artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- kernel: rhcos-<version>-live-kernel-<architecture>**
- initramfs: rhcos-<version>-live-initramfs.<architecture>.img**
- rootfs: rhcos-<version>-live-rootfs.<architecture>.img**

- Upload the **rootfs**, **kernel**, and **initramfs** files to your HTTP server.

IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

- Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.
- Configure PXE installation for the RHCOS images and begin the installation. Modify the following example menu entry for your environment and verify that the image and Ignition files are properly accessible:

```
DEFAULT pxeboot
TIMEOUT 20
PROMPT 0
LABEL pxeboot
KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> ①
APPEND initrd=http://<HTTP_server>/rhcos-<version>-live-initramfs.<architecture>.img
coreos.live.rootfs_url=http://<HTTP_server>/rhcos-<version>-live-rootfs.<architecture>.img
coreos.inst.install_dev=/dev/sda coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
② ③
```

① ② Specify the location of the live **kernel** file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

- 2 If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.
- 3 Specify the locations of the RHCOS files that you uploaded to your HTTP server. The `initrd` parameter value is the location of the `initramfs` file, the `coreos.live.rootfs_url` parameter value is the location of the `rootfs` file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the `APPEND` line to configure networking or other boot options.

NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `APPEND` line. For example, add `console=tty0 console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](#).

7. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.
9. Continue to create the machines for your cluster.

IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running **ssh core@<node>.<cluster_name>**. **<base_domain>** as a user with access to the SSH private key that is paired to the public key that you specified in your **install_config.yaml** file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

14.2.12.3. Enabling multipathing with kernel arguments on RHCOS

In OpenShift Container Platform 4.9 or later, during installation, you can enable multipathing for provisioned nodes. RHCOS supports multipathing on the primary disk. Multipathing provides added benefits of stronger resilience to hardware failure to achieve higher host availability.

During the initial cluster creation, you might want to add kernel arguments to all master or worker nodes. To add kernel arguments to master or worker nodes, you can create a **MachineConfig** object and inject that object into the set of manifest files used by Ignition during cluster setup.

Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir=<installation_directory>
```

2. Decide if you want to add kernel arguments to worker or master nodes.

- Create a machine config file. For example, create a **99-master-kargs-mpath.yaml** that instructs the cluster to add the **master** label and identify the multipath kernel argument:

```
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: "master"
  name: 99-master-kargs-mpath
spec:
  kernelArguments:
    - 'rd.multipath=default'
    - 'root=/dev/disk/by-label/dm-mpath-root'
```

3. To enable multipathing post-installation on worker nodes:

- Create a machine config file. For example, create a **99-worker-kargs-mpath.yaml** that instructs the cluster to add the **worker** label and identify the multipath kernel argument:

```
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
```

```

machineconfiguration.openshift.io/role: "worker"
name: 99-worker-kargs-mpath
spec:
kernelArguments:
- 'rd.multipath=default'
- 'root=/dev/disk/by-label/dm-mpath-root'
```

You can now continue on to create the cluster.

IMPORTANT

Additional post-installation steps are required to fully enable multipathing. For more information, see “Enabling multipathing with kernel arguments on RHCOS” in *Post-installation machine configuration tasks*.

In case of MPIO failure, use the bootlist command to update the boot device list with alternate logical device names. The command displays a boot list and it designates the possible boot devices for when the system is booted in normal mode.

- To display a boot list and specify the possible boot devices if the system is booted in normal mode, enter the following command:

```
$ bootlist -m normal -o
sda
```

- To update the boot list for normal mode and add alternate device names, enter the following command:

```
$ bootlist -m normal -o /dev/sdc /dev/sdd /dev/sde
sdc
sdd
sde
```

If the original boot disk path is down, the node reboots from the alternate device registered in the normal boot device list.

14.2.13. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

```
$ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \ ①
--log-level=info ②
```

- ① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.
- ② To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.22.1 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

IMPORTANT

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

14.2.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- ① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

- Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

14.2.15. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

- Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.22.1
master-1	Ready	master	63m	v1.22.1
master-2	Ready	master	64m	v1.22.1

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

- Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-8b2br	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
csr-8vnps	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
...			

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approvers** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	
Pending			
csr-c571v	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	
Pending			
...			

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	73m	v1.22.1
master-1	Ready	master	73m	v1.22.1
master-2	Ready	master	74m	v1.22.1
worker-0	Ready	worker	11m	v1.22.1
worker-1	Ready	worker	11m	v1.22.1

NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

14.2.16. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

- Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.9.0	True	False	False 19m
baremetal	4.9.0	True	False	False 37m
cloud-credential	4.9.0	True	False	False 40m
cluster-autoscaler	4.9.0	True	False	False 37m

service-ca	4.9.0	True	False	False 38m
storage	4.9.0	True	False	False 37m

- Configure the Operators that are not available.

14.2.16.1. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

14.2.16.1.1. Configuring registry storage for IBM Power Systems

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster on IBM Power Systems.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Container Storage.

IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

NOTE

When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry
```

NOTE

If the storage type is **emptyDIR**, the replica number cannot be greater than **1**.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

Example output

```
storage:  
pvc:  
claim:
```

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

```
$ oc edit configs.imageregistry/cluster
```

Then, change the line

```
managementState: Removed
```

to

```
managementState: Managed
```

14.2.16.1.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage":{"emptyDir":{}}}}'
```

WARNING

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

14.2.17. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.9.0	True	False	False 19m
baremetal	4.9.0	True	False	False 37m
cloud-credential	4.9.0	True	False	False 40m
cluster-autoscaler	4.9.0	True	False	False 37m
config-operator	4.9.0	True	False	False 38m
console	4.9.0	True	False	False 26m
csi-snapshot-controller	4.9.0	True	False	False 37m
dns	4.9.0	True	False	False 37m
etcd	4.9.0	True	False	False 36m
image-registry	4.9.0	True	False	False 31m
ingress	4.9.0	True	False	False 30m
insights	4.9.0	True	False	False 31m
kube-apiserver	4.9.0	True	False	False 26m
kube-controller-manager	4.9.0	True	False	False 36m
kube-scheduler	4.9.0	True	False	False 36m
kube-storage-version-migrator	4.9.0	True	False	False 37m
machine-api	4.9.0	True	False	False 29m
machine approver	4.9.0	True	False	False 37m
machine-config	4.9.0	True	False	False 36m
marketplace	4.9.0	True	False	False 37m
monitoring	4.9.0	True	False	False 29m
network	4.9.0	True	False	False 38m
node-tuning	4.9.0	True	False	False 37m
openshift-apiserver	4.9.0	True	False	False 32m
openshift-controller-manager	4.9.0	True	False	False 30m
openshift-samples	4.9.0	True	False	False 32m
operator-lifecycle-manager	4.9.0	True	False	False 37m
operator-lifecycle-manager-catalog	4.9.0	True	False	False 37m
operator-lifecycle-manager-packageserver	4.9.0	True	False	False 32m
service-ca	4.9.0	True	False	False 38m
storage	4.9.0	True	False	False 37m

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete ①
```

① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.

- a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

Example output

NAMESPACE	NAME	READY	STATUS
RESTARTS	AGE		
openshift-apiserver-operator	openshift-apiserver-operator-85cb746d55-zqhs8	1/1	
Running 1 9m			
openshift-apiserver	apiserver-67b9g	1/1	Running 0
3m			
openshift-apiserver	apiserver-ljcmx	1/1	Running 0
1m			
openshift-apiserver	apiserver-z25h4	1/1	Running 0
2m			
openshift-authentication-operator	authentication-operator-69d5d8bf84-vh2n8	1/1	
Running 0 5m			
...			

- b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> ①
```

- ① Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. Additional steps are required to enable multipathing. Do not enable multipathing during installation.

See "Enabling multipathing with kernel arguments on RHCOS" in the *Post-installation machine configuration tasks* documentation for more information.

14.2.18. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

14.2.19. Next steps

- [Enabling multipathing with kernel arguments on RHCOS](#) .
- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#) .

14.3. INSTALLING A CLUSTER ON IBM POWER SYSTEMS IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.9, you can install a cluster on IBM Power Systems infrastructure that you provision in a restricted network.

IMPORTANT

Additional considerations exist for non-bare metal platforms. Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you install an OpenShift Container Platform cluster.

14.3.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [created a mirror registry for installation in a restricted network](#) and obtained the **imageContentSources** data for your version of OpenShift Container Platform.
- Before you begin the installation process, you must move or remove any existing installation files. This ensures that the required installation files are created and updated during the installation process.

IMPORTANT

Ensure that installation steps are performed on a machine with access to the installation media.

- You provisioned [persistent storage](#) for your cluster. To deploy a private image registry, your storage must provide **ReadWriteMany** access modes.
- If you use a firewall and plan to use the Telemetry service, you [configured the firewall to allow the sites](#) that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

14.3.2. About installations in restricted networks

In OpenShift Container Platform 4.9, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

14.3.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

14.3.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

14.3.4. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

14.3.4.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

Table 14.18. Minimum required hosts

Hosts	Description
One temporary bootstrap machine	The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.
Three control plane machines	The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.
At least two compute machines, which are also known as worker machines.	The workloads requested by OpenShift Container Platform users run on the compute machines.

IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 7.9, or RHEL 8.4.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

14.3.4.2. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

Machine	Operating System	vCPU [1]	Virtual RAM	Storage	IOPS [2]
Bootstrap	RHCOS	2	16 GB	100 GB	300
Control plane	RHCOS	2	16 GB	100 GB	300
Compute	RHCOS	2	8 GB	100 GB	300

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

14.3.4.3. Minimum IBM Power Systems requirements

You can install OpenShift Container Platform version 4.9 on the following IBM hardware:

- IBM POWER8 or POWER9 processor-based systems

Hardware requirements

- 6 IBM Power bare metal servers or 6 LPARs across multiple PowerVM servers

Operating system requirements

- One instance of an IBM POWER8 or POWER9 processor-based system

On your IBM Power instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

Disk storage for the IBM Power guest virtual machines

- Storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

Network for the PowerVM guest virtual machines

- Virtualized by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM vNIC

Storage / main memory

- 100 GB / 16 GB for OpenShift Container Platform control plane machines
- 100 GB / 8 GB for OpenShift Container Platform compute machines
- 100 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

14.3.4.4. Recommended IBM Power system requirements

Hardware requirements

- 6 IBM Power bare metal servers or 6 LPARs across multiple PowerVM servers

Operating system requirements

- One instance of an IBM POWER8 or POWER9 processor-based system

On your IBM Power instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

Disk storage for the IBM Power guest virtual machines

- Storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

Network for the PowerVM guest virtual machines

- Virtualized by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM vNIC

Storage / main memory

- 120 GB / 32 GB for OpenShift Container Platform control plane machines
- 120 GB / 32 GB for OpenShift Container Platform compute machines
- 120 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

14.3.4.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using

kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

14.3.4.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.

NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

14.3.4.6.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

14.3.4.6.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

Table 14.19. Ports used for all-machine to all-machine communications

Protocol	Port	Description
ICMP	N/A	Network reachability tests
TCP	1936	Metrics
	9000-9999	Host level services, including the node exporter on ports 9100-9101 and the Cluster Version Operator on port 9099 .
	10250-10259	The default ports that Kubernetes reserves
	10256	openshift-sdn
UDP	4789	VXLAN and Geneve
	6081	VXLAN and Geneve
	9000-9999	Host level services, including the node exporter on ports 9100-9101 .
TCP/UDP	30000-32767	Kubernetes node port

Table 14.20. Ports used for all-machine to control plane communications

Protocol	Port	Description
TCP	6443	Kubernetes API

Table 14.21. Ports used for control plane machine to control plane machine communications

Protocol	Port	Description
TCP	2379-2380	etcd server and peer ports

NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service* .

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

Additional resources

- [Configuring chrony time service](#)

14.3.4.7. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

NOTE

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the *DHCP recommendations for user-provisioned infrastructure* section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, **<cluster_name>** is the cluster name and **<base_domain>** is the base domain that you specify in the **install-config.yaml** file. A complete DNS record takes the form: **<component>.<cluster_name>.<base_domain>..**

Table 14.22. Required DNS records

Component	Record	Description
Kubernetes API	api.<cluster_name>.<base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.
	api-int.<cluster_name>.<base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.

IMPORTANT

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.

Component	Record	Description
Routes	*.apps.<cluster_name>. <base_domain>.	A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.<cluster_name>. <base_domain> is used as a wildcard route to the OpenShift Container Platform console.
Bootstrap machine	bootstrap.<cluster_name>. <base_domain>.	A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.
Control plane machines	<master><n>. <cluster_name>. <base_domain>.	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.
Compute machines	<worker><n>. <cluster_name>. <base_domain>.	DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

NOTE

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

TIP

You can use the **dig** command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

14.3.4.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is **ocp4** and the base domain is **example.com**.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

Example 14.4. Sample DNS zone database

```

11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. ⑦
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. ⑧
;
:EOF
```

- ① Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
- ② Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
- ③ Provides reverse DNS resolution for the bootstrap machine.
- ④ ⑤ ⑥ Provides reverse DNS resolution for the control plane machines.
- ⑦ ⑧ Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

14.3.4.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

- API load balancer.** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
 - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
 - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**NOTE**

Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

Table 14.23. API load balancer

Port	Back-end machines (pool members)	Internal	External	Description
6443	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.	X	X	Kubernetes API server
22623	Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.	X		Machine config server

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the **/readyz** endpoint to the removal of the API server instance from the pool. Within the time frame after **/readyz** returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. Application ingress load balancer. Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 14.24. Application ingress load balancer

Port	Back-end machines (pool members)	Internal	External	Description
443	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTPS traffic
80	The machines that run the Ingress Controller pods, compute, or worker, by default.	X	X	HTTP traffic

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

NOTE

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

14.3.4.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an **/etc/haproxy/haproxy.cfg** configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 14.6. Sample API and application ingress load balancer configuration

```

global
  log    127.0.0.1 local2
  pidfile /var/run/haproxy.pid
  maxconn 4000
  daemon
defaults
  mode      http
  log       global
  option    dontlognull
  option http-server-close
  option    redispatch
  retries   3
  timeout http-request 10s
  timeout queue     1m
  timeout connect   10s
  timeout client    1m
  timeout server    1m
  timeout http-keep-alive 10s
  timeout check     10s
  maxconn   3000

  log       global
  maxconn 10
  stats enable
  stats hide-version
  stats refresh 30s
  stats show-node
  stats show-desc Stats for ocp4 cluster ①
  stats auth admin:ocp4
  stats uri /stats
listen api-server-6443 ②
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup ③
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623 ④
  bind *:22623
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup ⑤
  server master0 master0.ocp4.example.com:22623 check inter 1s
  server master1 master1.ocp4.example.com:22623 check inter 1s
  server master2 master2.ocp4.example.com:22623 check inter 1s

```

```

listen ingress-router-443 6
  bind *:443
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:443 check inter 1s
  server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80 7
  bind *:80
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:80 check inter 1s
  server worker1 worker1.ocp4.example.com:80 check inter 1s

```

- 1** In the example, the cluster name is **ocp4**.
- 2** Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
- 3** **5** The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.
- 4** Port **22623** handles the machine config server traffic and points to the control plane machines.
- 6** Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
- 7** Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltpu** on the HAProxy node.

NOTE

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy_connect_any=1**.

14.3.5. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in

preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

Prerequisites

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
 - a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
 - b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

NOTE

If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

- c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the *Setting the cluster node hostnames through DHCP* section for details about hostname considerations.

NOTE

If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.
3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.
4. Setup the required DNS infrastructure for your cluster.

- a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
 - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.
See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.
5. Validate your DNS configuration.
 - a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
 - b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.
See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.
 6. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

14.3.6. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
 - a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> ①
```

- ① Replace **<nameserver_ip>** with the IP address of the nameserver, **<cluster_name>** with your cluster name, and **<base_domain>** with your base domain name.

Example output

```
api.ocp4.example.com. 0 IN A 192.168.1.5
```

- b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

```
api-int.ocp4.example.com. 0 IN A 192.168.1.5
```

- c. Test an example ***.apps.<cluster_name>.<base_domain>** DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

```
random.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace **random** with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

- d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

- e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
- 2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.
 - a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. ①
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. ②
```

- ① Provides the record name for the Kubernetes internal API.
- ② Provides the record name for the Kubernetes API.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

- b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

- c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

14.3.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **./openshift-install gather** command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> ①
```

- 1 Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the **./openshift-install gather** command.

NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

■

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> ①
```

- ① Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

14.3.8. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation_directory>**.

NOTE

You must name this configuration file **install-config.yaml**.

NOTE

For some platform types, you can alternatively run `./openshift-install create install-config --dir=<installation_directory>` to generate an **install-config.yaml** file. You can provide details about your cluster configuration at the prompts.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

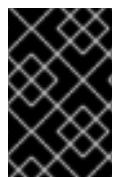

14.3.8.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized **install-config.yaml** installation configuration file that describes the details for your environment.

NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

IMPORTANT

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

14.3.8.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 14.25. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>, <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}} .	String of lowercase letters, hyphens (-), and periods (.), such as dev .
platform	The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere , or {} . For additional information about platform , <platform> parameters, consult the table for your specific platform that follows.	Object

Parameter	Description	Values
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths": { "cloud.openshift.com": { "auth": "b3Blb=", "email": "you@example.com" }, "quay.io": { "auth": "b3Blb=", "email": "you@example.com" } } }</pre>

14.3.8.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 14.26. Network parameters

Parameter	Description	Values
networking	The configuration for the cluster network.	 Object NOTE You cannot modify parameters specified by the networking object after installation.
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23 . If you specify multiple IP address blocks, the blocks must not overlap.	An array of objects. For example: <pre> networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23 </pre>

Parameter	Description	Values
networking.clusterNetwork.cidr	Required if you use networking.clusterNetwork . An IP address block. An IPv4 network.	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a / 23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{(32 - 23)} - 2$) pod IP addresses.	A subnet prefix. The default value is 23 .
networking.serviceNetwork	The IP address block for services. The default value is 172.30.0.0/16 . The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.	An array with an IP address block in CIDR format. For example: networking: serviceNetwork: - 172.30.0.0/16
networking.machineNetwork	The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.	An array of objects. For example: networking: machineNetwork: - cidr: 10.0.0.0/16
networking.machineNetwork.cidr	Required if you use networking.machineNetwork . An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24 .	An IP network block in CIDR notation. For example, 10.0.0.0/16 .

**NOTE**

Set the **networking.machineNetwork** to match the CIDR that the preferred NIC resides in.

14.3.8.1.3. Optional configuration parameters

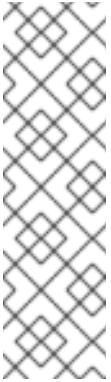

Optional installation configuration parameters are described in the following table:

Table 14.27. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are ppc64le (the default).	String
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .

Parameter	Description	Values
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are ppc64le (the default).	String
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	<p>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</p> 	<p>Mint, Passthrough, Manual, or an empty string ("").</p> <p>NOTE</p> <p>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the <i>Cloud Credential Operator</i> entry in the <i>Red Hat Operators</i> reference content.</p>
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	<p>false or true</p>

Parameter	Description	Values
imageContentSources	Sources and repositories for the release-image content.	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.	Internal or External . The default value is External . Setting this field to Internal is not supported on non-cloud platforms.
sshKey	The SSH key or keys to authenticate access your cluster machines.  NOTE For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.	One or more keys. For example: sshKey: <key1> <key2> <key3>

14.3.8.2. Sample `install-config.yaml` file for IBM Power Systems

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```
apiVersion: v1
baseDomain: example.com 1
compute: 2
- hyperthreading: Enabled 3
  name: worker
replicas: 0 4
  architecture : ppc64le
controlPlane: 5
    hyperthreading: Enabled 6
```

- 1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.
 - 2 5 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.
 - 3 6 Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

IMPORTANT

If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

- 4** You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute

NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

- 7** The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.
- 8** The cluster name that you specified in your DNS records.
- 9** A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.
- 10** The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to **23**, then each node is assigned a /23 subnet out of the given **cidr**, which allows for 510 ($2^{(32 - 23)} - 2$) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.
- 11** The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.
- 12** You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Power Systems infrastructure.

WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as [installing a cluster on any platform](#), and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.
2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

- 13** Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

- 14 For **<local_registry>**, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, **registry.example.com** or **registry.example.com:5000**. For **<credentials>**, specify the base64-encoded user name and password for your mirror registry.
- 15 The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- 16 Provide the contents of the certificate file that you used for your mirror registry.
- 17 Provide the **imageContentSources** section from the output of the command to mirror the repository.

14.3.8.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

- If your cluster is on AWS, you added the **ec2.<region>.amazonaws.com**, **elasticloadbalancing.<region>.amazonaws.com**, and **s3.<region>.amazonaws.com** endpoints to your VPC endpoint. These endpoints are required to complete requests from the

nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

- 1 Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ①
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
  noProxy: example.com ③
  additionalTrustBundle: | ④
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
...
...
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpProxy** value.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpsProxy** value.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use `*` to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace to hold the additional CA certificates. If you provide **additionalTrustBundle** and at least one proxy setting, the **Proxy** object is configured to reference the **user-ca-bundle** config map in the **trustedCA** field. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges the contents specified for the **trustedCA** parameter with the RHCOS trust bundle. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE

The installation program does not support the proxy **readinessEndpoints** field.

- 2 Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

14.3.8.4. Configuring a three-node cluster

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing **install-config.yaml** file.

Procedure

- Ensure that the number of compute replicas is set to **0** in your **install-config.yaml** file, as shown in the following **compute** stanza:

```
compute:  
  - name: worker  
    platform: {}  
    replicas: 0
```

NOTE

You must set the value of the **replicas** parameter for the compute machines to **0** when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.
- When you create the Kubernetes manifest files in the following procedure, ensure that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file is set to **true**. This enables your application workloads to run on the control plane nodes.
- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

14.3.9. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named **cluster**. The CR specifies the fields for the **Network** API in the **operator.openshift.io** API group.

The CNO configuration inherits the following fields during cluster installation from the **Network** API in the **Network.config.openshift.io** API group and these fields cannot be changed:

clusterNetwork

IP address pools from which pod IP addresses are allocated.

serviceNetwork

IP address pool for services.

defaultNetwork.type

Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

14.3.9.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

Table 14.28. Cluster Network Operator configuration object

Field	Type	Description
metadata.name	string	The name of the CNO object. This name is always cluster .
spec.clusterNetwork	array	<p>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</p> <pre> spec: clusterNetwork: - cidr: 10.128.0.0/19 hostPrefix: 23 - cidr: 10.128.32.0/19 hostPrefix: 23 </pre> <p>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</p>

Field	Type	Description
spec.serviceNetwork	array	<p>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:</p> <pre>spec: serviceNetwork: - 172.30.0.0/14</pre> <p>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</p>
spec.defaultNetwork	object	Configures the Container Network Interface (CNI) cluster network provider for the cluster network.
spec.kubeProxyConfig	object	The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

defaultNetwork object configuration

The values for the **defaultNetwork** object are defined in the following table:

Table 14.29. **defaultNetwork** object

Field	Type	Description
type	string	<p>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</p> <p> NOTE</p> <p>OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.</p>
openshiftSDNConfig	object	This object is only valid for the OpenShift SDN cluster network provider.
ovnKubernetesConfig	object	This object is only valid for the OVN-Kubernetes cluster network provider.

Configuration for the OpenShift SDN CNI cluster network provider

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

Table 14.30. `openshiftSDNConfig` object

Field	Type	Description
mode	string	<p>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy.</p> <p>The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</p>
mtu	integer	<p>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.</p> <p>This value cannot be changed after cluster installation.</p>
vxlanPort	integer	<p>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.</p> <p>If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.</p> <p>On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</p>

Example OpenShift SDN configuration

```
defaultNetwork:
type: OpenShiftSDN
openshiftSDNConfig:
  mode: NetworkPolicy
  mtu: 1450
  vxlanPort: 4789
```

Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

Table 14.31. ovnKubernetesConfig object

Field	Type	Description
mtu	integer	<p>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.</p> <p>This value cannot be changed after cluster installation.</p>
genevePort	integer	The port to use for all Geneve packets. The default value is 6081 . This value cannot be changed after cluster installation.
ipsecConfig	object	Specify an empty object to enable IPsec encryption. This value cannot be changed after cluster installation.
policyAuditConfig	object	Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.

Table 14.32. policyAuditConfig object

Field	Type	Description
rateLimit	integer	The maximum number of messages to generate every second per node. The default value is 20 messages per second.
maxFileSize	integer	The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.

Field	Type	Description
destination	string	<p>One of the following additional audit log targets:</p> <ul style="list-style-type: none"> libc The libc syslog() function of the journald process on the host. udp:<host>:<port> A syslog server. Replace <host>:<port> with the host and port of the syslog server. unix:<file> A Unix Domain Socket file specified by <file>. null Do not send the audit logs to any additional target.
syslogFacility	string	The syslog facility, such as kern , as defined by RFC5424. The default value is local0 .

Example OVN-Kubernetes configuration

```
defaultNetwork:
type: OVNKubernetes
ovnKubernetesConfig:
  mtu: 1400
  genevePort: 6081
  ipsecConfig: {}
```

kubeProxyConfig object configuration

The values for the **kubeProxyConfig** object are defined in the following table:

Table 14.33. **kubeProxyConfig** object

Field	Type	Description
iptablesSyncPeriod	string	<p>The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</p> <div style="display: flex; align-items: center; justify-content: space-between;"> <div style="flex-grow: 1; margin-right: 20px;">  </div> <div> NOTE <p>Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary.</p> </div> </div>

Field	Type	Description
proxyArguments.iptables-min-sync-period	array	<p>The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s, m, and h and are described in the Go time package. The default value is:</p> <pre>kubeProxyConfig: proxyArguments: iptables-min-sync-period: - 0s</pre>

14.3.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the [client image mirror](#). The Linux version of the installation program runs on ppc64le only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the **install-config.yaml** installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

Example output

```
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift
```

- For <installation_directory>, specify the installation directory that contains the **install-config.yaml** file you created.

WARNING

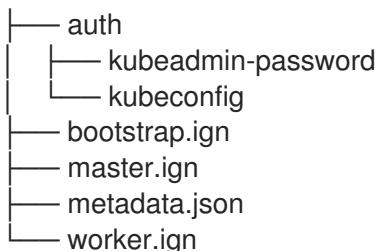

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

- Check that the **mastersSchedulable** parameter in the <installation_directory>/manifests/cluster-scheduler-02-config.yml Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
 - Open the <installation_directory>/manifests/cluster-scheduler-02-config.yml file.
 - Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
 - Save and exit the file.
- To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory> ①
```

- For <installation_directory>, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the <installation_directory>/auth directory:

14.3.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Power Systems infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

Follow either the steps to use an ISO image or network PXE booting to install RHCOS on the machines.

14.3.11.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your **bootstrap.ign** Ignition config file:

```
$ sha512sum <installation_directory>/bootstrap.ign
```

Example output

```
a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf011  
6e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b  
installation_directory/bootstrap.ign
```

The digests are provided to the **coreos-installer** in a later step to validate the authenticity of the Ignition config files on the cluster nodes.

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

- From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign ①
```

Example output

```
% Total % Received % Xferd Average Speed Time Time Time Current
          Dload Upload Total Spent Left Speed
0 0 0 0 0 0 0 --:--:--:--:--:--:--:--:-- 0{"ignition": {"version": "3.2.0"}, "passwd": {"users": [{"name": "core", "sshAuthorizedKeys": ["ssh-rsa...}}
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

- Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

rhcos-<version>-live.<architecture>.iso

- Use the ISO to start the RHCOS installation. Use one of the following installation options:
 - Burn the ISO image to a disk and boot it directly.
 - Use ISO redirection by using a lights-out management (LOM) interface.
- Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

NOTE

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the **coreos-installer** command as outlined in the following steps, instead of adding kernel arguments.

- Run the **coreos-installer** command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device>
--ignition-hash=SHA512-<digest> ①②
```

- 1 1** You must run the **coreos-installer** command by using **sudo**, because the **core** user does not have the required root privileges to perform the installation.
- 2** The **--ignition-hash** option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. **<digest>** is the Ignition config file SHA512 digest obtained in a preceding step.

NOTE

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running **coreos-installer**.

The following example initializes a bootstrap node installation to the **/dev/sda** device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```
$ sudo coreos-installer install --ignition-
url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-
hash=SHA512-
a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf011
6e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.

10. Continue to create the other machines for your cluster.

IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

NOTE

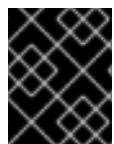

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running **ssh core@<node>.<cluster_name>**. **<base_domain>** as a user with access to the SSH private key that is paired to the public key that you specified in your **install_config.yaml** file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

14.3.11.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the **coreos-installer** command.

14.3.11.1.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

IMPORTANT

When adding networking arguments manually, you must also add the **rd.neednet=1** kernel argument to bring the network up in the initramfs.

The following table provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the **ip=**, **nameserver=**, and **bond=** kernel arguments.

NOTE

Ordering is important when adding the kernel arguments: **ip=**, **nameserver=**, and then **bond=**.

The networking options are passed to the **dracut** tool during system boot. For more information about the networking options supported by **dracut**, see the **dracut.cmdline** manual page.

Table 14.34. Networking and bonding options for ISO installations

Description	Examples
<p>To configure an IP address, either use DHCP (ip=dhcp) or set an individual static IP address (ip=<host_ip>). If setting a static IP, you must then identify the DNS server IP address (nameserver=<dns_ip>) on each node. This example sets:</p> <ul style="list-style-type: none"> • The node's IP address to 10.10.10.2 • The gateway address to 10.10.10.254 • The netmask to 255.255.255.0 • The hostname to core0.example.com • The DNS server address to 4.4.4.41 • The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically. 	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none nameserver=4.4.4.41</pre>
 <p>NOTE</p> <p>When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.</p>	
<p>Specify multiple network interfaces by specifying multiple ip= entries.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none</pre>
<p>Optional: You can configure routes to additional networks by setting an rd.route= value.</p> <p>If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.</p>	<p>To configure the default gateway:</p> <pre>ip=:10.10.10.254:::</pre> <p>To configure the route for the additional network:</p> <pre>rd.route=20.20.20.0/24:20.20.20.254:enp2s0</pre>
<p>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the enp1s0 interface has a static networking configuration and DHCP is disabled for enp2s0, which is not used.</p>	<pre>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ip=:core0.example.com:enp2s0:none</pre>

Description	Examples
<p>You can combine DHCP and static IP configurations on systems with multiple network interfaces.</p>	<pre data-bbox="822 265 1440 363">ip=enp1s0:dhcp ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp2s0:none</pre>
<p>Optional: You can configure VLANs on individual interfaces by using the vlan= parameter.</p>	<p>To configure a VLAN on a network interface and use a static IP address:</p> <pre data-bbox="853 541 1440 640">ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:enp2s0.100:none vlan=enp2s0.100:enp2s0</pre> <p>To configure a VLAN on a network interface and to use DHCP:</p> <pre data-bbox="853 810 1171 887">ip=enp2s0.100:dhcp vlan=enp2s0.100:enp2s0</pre>
<p>You can provide multiple DNS servers by adding a nameserver= entry for each server.</p>	<pre data-bbox="853 1051 1107 1118">nameserver=1.1.1.1 nameserver=8.8.8.8</pre>
<p>Optional: Bonding multiple network interfaces to a single interface is supported using the bond= option. In these two examples:</p> <ul style="list-style-type: none"> • The syntax for configuring a bonded interface is: bond=name[:network_interfaces] [:options] <i>name</i> is the bonding device name (bond0), <i>network_interfaces</i> represents a comma-separated list of physical (ethernet) interfaces (em1,em2), and <i>options</i> is a comma-separated list of bonding options. Enter modinfo bonding to see available options. • When you create a bonded interface using bond=, you must specify how the IP address is assigned and other information for the bonded interface. 	<p>To configure the bonded interface to use DHCP, set the bond's IP address to dhcp. For example:</p> <pre data-bbox="853 1298 1414 1374">bond=bond0:em1,em2:mode=active-backup ip=bond0:dhcp</pre> <p>To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:</p> <pre data-bbox="853 1567 1440 1666">bond=bond0:em1,em2:mode=active-backup ip=10.10.10.2::10.10.10.254:255.255.255.0:co re0.example.com:bond0:none</pre>

Description	Examples
Optional: You can configure VLANs on bonded interfaces by using the vlan= parameter.	To configure the bonded interface with a VLAN and to use DHCP: ip=bond0.100:dhcp bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0
	To configure the bonded interface with a VLAN and to use a static IP address: ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0.100:none bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0

14.3.11.2. Installing RHCOS by using PXE booting

You can use PXE booting to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign ①
```

Example output

```
% Total % Received % Xferd Average Speed Time Time Time Current
          Dload Upload Total Spent Left Speed
0 0 0 0 0 0 0 0 --:--:-- --:--:-- --:--:-- 0{"ignition": "version": "3.2.0"}, "passwd": {"users": [{"name": "core", "sshAuthorizedKeys": ["ssh-rsa...
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Obtain the RHCOS **kernel**, **initramfs** and **rootfs** files from the [RHCOS image mirror](#) page.

IMPORTANT

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate **kernel**, **initramfs**, and **rootfs** artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- kernel: rhcos-<version>-live-kernel-<architecture>
 - initramfs: rhcos-<version>-live-initramfs.<architecture>.img
 - rootfs: rhcos-<version>-live-rootfs.<architecture>.img

4. Upload the **rootfs**, **kernel**, and **initramfs** files to your HTTP server.

IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.
 6. Configure PXE installation for the RHCOS images and begin the installation.
Modify the following example menu entry for your environment and verify that the image and Ignition files are properly accessible:

```
DEFAULT pxeboot
TIMEOUT 20
PROMPT 0
LABEL pxeboot
    KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> ①
    APPEND initrd=http://<HTTP_server>/rhcos-<version>-live-initramfs.<architecture>.img
coreos.live.rootfs_url=http://<HTTP_server>/rhcos-<version>-live-rootfs.<architecture>.img
coreos.inst.install_dev=/dev/sda coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
② ③
```

1 1 Specify the location of the live **kernel** file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

- 2 If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.
- 3 Specify the locations of the RHCOS files that you uploaded to your HTTP server. The `initrd` parameter value is the location of the `initramfs` file, the `coreos.live.rootfs_url` parameter value is the location of the `rootfs` file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the `APPEND` line to configure networking or other boot options.

NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `APPEND` line. For example, add `console=tty0 console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](#).

7. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.
9. Continue to create the machines for your cluster.

IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running **ssh core@<node>.<cluster_name>**. **<base_domain>** as a user with access to the SSH private key that is paired to the public key that you specified in your **install_config.yaml** file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

14.3.11.3. Enabling multipathing with kernel arguments on RHCOS

In OpenShift Container Platform 4.9 or later, during installation, you can enable multipathing for provisioned nodes. RHCOS supports multipathing on the primary disk. Multipathing provides added benefits of stronger resilience to hardware failure to achieve higher host availability.

During the initial cluster creation, you might want to add kernel arguments to all master or worker nodes. To add kernel arguments to master or worker nodes, you can create a **MachineConfig** object and inject that object into the set of manifest files used by Ignition during cluster setup.

Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir=<installation_directory>
```

2. Decide if you want to add kernel arguments to worker or master nodes.

- Create a machine config file. For example, create a **99-master-kargs-mpath.yaml** that instructs the cluster to add the **master** label and identify the multipath kernel argument:

```
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: "master"
  name: 99-master-kargs-mpath
spec:
  kernelArguments:
    - 'rd.multipath=default'
    - 'root=/dev/disk/by-label/dm-mpath-root'
```

3. To enable multipathing post-installation on worker nodes:

- Create a machine config file. For example, create a **99-worker-kargs-mpath.yaml** that instructs the cluster to add the **worker** label and identify the multipath kernel argument:

```
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
```

```

    machineconfiguration.openshift.io/role: "worker"
    name: 99-worker-kargs-mpath
    spec:
      kernelArguments:
        - 'rd.multipath=default'
        - 'root=/dev/disk/by-label/dm-mpath-root'

```

You can now continue on to create the cluster.

IMPORTANT

Additional post-installation steps are required to fully enable multipathing. For more information, see “Enabling multipathing with kernel arguments on RHCOS” in *Post-installation machine configuration tasks*.

In case of MPIO failure, use the bootlist command to update the boot device list with alternate logical device names. The command displays a boot list and it designates the possible boot devices for when the system is booted in normal mode.

- To display a boot list and specify the possible boot devices if the system is booted in normal mode, enter the following command:

```
$ bootlist -m normal -o
sda
```

- To update the boot list for normal mode and add alternate device names, enter the following command:

```
$ bootlist -m normal -o /dev/sdc /dev/sdd /dev/sde
sdc
sdd
sde
```

If the original boot disk path is down, the node reboots from the alternate device registered in the normal boot device list.

14.3.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

Procedure

- Monitor the bootstrap process:

```
$ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \ ①
--log-level=info ②
```

- For **<installation_directory>**, specify the path to the directory that you stored the installation files in.
- To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.22.1 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

- After bootstrap process is complete, remove the bootstrap machine from the load balancer.

IMPORTANT

You must remove the bootstrap machine from the load balancer at this point.
You can also remove or reformat the bootstrap machine itself.

14.3.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

- Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- For **<installation_directory>**, specify the path to the directory that you stored the installation files in.
- Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

14.3.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.22.1
master-1	Ready	master	63m	v1.22.1
master-2	Ready	master	64m	v1.22.1

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-8b2br	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
csr-8vnps	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
...			

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approvers** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	
Pending			
csr-c571v	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	
Pending			
...			

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	73m	v1.22.1
master-1	Ready	master	73m	v1.22.1
master-2	Ready	master	74m	v1.22.1
worker-0	Ready	worker	11m	v1.22.1
worker-1	Ready	worker	11m	v1.22.1

NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

14.3.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

- Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME SINCE	VERSION	AVAILABLE	PROGRESSING	DEGRADED
authentication	4.9.0	True	False	False 19m
baremetal	4.9.0	True	False	False 37m
cloud-credential	4.9.0	True	False	False 40m
cluster-autoscaler	4.9.0	True	False	False 37m
config-operator	4.9.0	True	False	False 38m
console	4.9.0	True	False	False 26m
csi-snapshot-controller	4.9.0	True	False	False 37m
dns	4.9.0	True	False	False 37m
etcd	4.9.0	True	False	False 36m
image-registry	4.9.0	True	False	False 31m
ingress	4.9.0	True	False	False 30m
insights	4.9.0	True	False	False 31m
kube-apiserver	4.9.0	True	False	False 26m
kube-controller-manager	4.9.0	True	False	False 36m
kube-scheduler	4.9.0	True	False	False 36m
kube-storage-version-migrator	4.9.0	True	False	False 37m
machine-api	4.9.0	True	False	False 29m
machine-approver	4.9.0	True	False	False 37m
machine-config	4.9.0	True	False	False 36m
marketplace	4.9.0	True	False	False 37m
monitoring	4.9.0	True	False	False 29m
network	4.9.0	True	False	False 38m
node-tuning	4.9.0	True	False	False 37m
openshift-apiserver	4.9.0	True	False	False 32m
openshift-controller-manager	4.9.0	True	False	False 30m
openshift-samples	4.9.0	True	False	False 32m
operator-lifecycle-manager	4.9.0	True	False	False 37m
operator-lifecycle-manager-catalog	4.9.0	True	False	False 37m
operator-lifecycle-manager-packageserver	4.9.0	True	False	False 32m
service-ca	4.9.0	True	False	False 38m
storage	4.9.0	True	False	False 37m

- Configure the Operators that are not available.

14.3.15.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding **disableAllDefaultSources: true** to the **OperatorHub** object:

```
$ oc patch OperatorHub cluster --type json \
-p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
```

TIP

Alternatively, you can use the web console to manage catalog sources. From the **Administration → Cluster Settings → Global Configuration → OperatorHub** page, click the **Sources** tab, where you can create, delete, disable, and enable individual sources.

14.3.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

14.3.15.2.1. Changing the image registry's management state

To start the image registry, you must change the Image Registry Operator configuration's **managementState** from **Removed** to **Managed**.

Procedure

- Change **managementState** Image Registry Operator configuration from **Removed** to **Managed**. For example:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"managementState": "Managed"}}'
```

14.3.15.2.2. Configuring registry storage for IBM Power Systems

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster on IBM Power Systems.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Container Storage.

IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

NOTE

When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry
```

NOTE

If the storage type is **emptyDIR**, the replica number cannot be greater than **1**.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

Example output

```
storage:  
pvc:  
claim:
```

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

```
$ oc edit configs.imageregistry/cluster
```

Then, change the line

```
managementState: Removed
```

—
to

managementState: Managed

14.3.15.2.3. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage":{"emptyDir":{}}}}'
```

WARNING

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

14.3.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

NAME	VERSION	AVAILABLE	PROGRESSING	DEGRADED
------	---------	-----------	-------------	----------

SINCE						
authentication	4.9.0	True	False	False	19m	
baremetal	4.9.0	True	False	False	37m	
cloud-credential	4.9.0	True	False	False	40m	
cluster-autoscaler	4.9.0	True	False	False	37m	
config-operator	4.9.0	True	False	False	38m	
console	4.9.0	True	False	False	26m	
csi-snapshot-controller		4.9.0	True	False	False	37m
dns	4.9.0	True	False	False	37m	
etcd	4.9.0	True	False	False	36m	
image-registry		4.9.0	True	False	False	31m
ingress	4.9.0	True	False	False	30m	
insights	4.9.0	True	False	False	31m	
kube-apiserver		4.9.0	True	False	False	26m
kube-controller-manager			4.9.0	True	False	36m
kube-scheduler			4.9.0	True	False	36m
kube-storage-version-migrator			4.9.0	True	False	False
machine-api	4.9.0	True	False	False	29m	
machine-approver		4.9.0	True	False	False	37m
machine-config		4.9.0	True	False	False	36m
marketplace		4.9.0	True	False	False	37m
monitoring	4.9.0	True	False	False	29m	
network	4.9.0	True	False	False	38m	
node-tuning		4.9.0	True	False	False	37m
openshift-apiserver		4.9.0	True	False	False	32m
openshift-controller-manager			4.9.0	True	False	30m
openshift-samples			4.9.0	True	False	32m
operator-lifecycle-manager			4.9.0	True	False	False
operator-lifecycle-manager-catalog		4.9.0	True	False	False	37m
operator-lifecycle-manager-packageserver		4.9.0	True	False	False	32m
service-ca	4.9.0	True	False	False	38m	
storage	4.9.0	True	False	False	37m	

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete ①
```

- ① For <installation_directory>, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.

- a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

Example output

NAMESPACE	NAME	READY	STATUS
RESTARTS	AGE		
openshift-apiserver-operator	openshift-apiserver-operator-85cb746d55-zqhs8	1/1	
Running 1 9m			
openshift-apiserver	apiserver-67b9g	1/1	Running 0
3m			
openshift-apiserver	apiserver-ljcmx	1/1	Running 0
1m			
openshift-apiserver	apiserver-z25h4	1/1	Running 0
2m			
openshift-authentication-operator	authentication-operator-69d5d8bf84-vh2n8	1/1	
Running 0 5m			
...			

- b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> ①
```

- ① Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. Additional steps are required to enable multipathing. Do not enable multipathing during installation.

See "Enabling multipathing with kernel arguments on RHCOS" in the *Post-installation machine configuration tasks* documentation for more information.

4. Register your cluster on the [Cluster registration](#) page.

14.3.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

14.3.18. Next steps

- [Enabling multipathing with kernel arguments on RHCOS](#) .
- [Customize your cluster](#).
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by [configuring additional trust stores](#).

CHAPTER 15. INSTALLING ON OPENSTACK

15.1. PREPARING TO INSTALL ON OPENSTACK

15.1.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).

15.1.2. Choosing a method to install OpenShift Container Platform on OpenStack

You can install OpenShift Container Platform on installer-provisioned or user-provisioned infrastructure. The default installation type uses installer-provisioned infrastructure, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provision. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See [Installation process](#) for more information about installer-provisioned and user-provisioned installation processes.

15.1.2.1. Installing a cluster on installer-provisioned infrastructure

You can install a cluster on Red Hat OpenStack Platform (RHOSP) infrastructure that is provisioned by the OpenShift Container Platform installation program, by using one of the following methods:

- **[Installing a cluster on OpenStack with customizations](#)** You can install a customized cluster on RHOSP. The installation program allows for some customization to be applied at the installation stage. Many other customization options are available [post-installation](#).
- **[Installing a cluster on OpenStack with Kuryr](#)** You can install a customized OpenShift Container Platform cluster on RHOSP that uses Kuryr SDN. Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.
- **[Installing a cluster on OpenStack in a restricted network](#)** You can install OpenShift Container Platform on RHOSP in a restricted or disconnected network by creating an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

15.1.2.2. Installing a cluster on user-provisioned infrastructure

You can install a cluster on RHOSP infrastructure that you provision, by using one of the following methods:

- **[Installing a cluster on OpenStack on your own infrastructure](#)** You can install OpenShift Container Platform on user-provisioned RHOSP infrastructure. By using this installation method, you can integrate your cluster with existing infrastructure and modifications. For

installations on user-provisioned infrastructure, you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. You can use the provided Ansible playbooks to assist with the deployment process.

- **Installing a cluster on OpenStack with Kuryr on your own infrastructure** You can install OpenShift Container Platform on user-provisioned RHOSP infrastructure that uses Kuryr SDN.
- **Installing a cluster on OpenStack on your own SR-IOV infrastructure** You can install OpenShift Container Platform on user-provisioned RHOSP infrastructure that uses single-root input/output virtualization (SR-IOV) networks to run compute machines.

15.2. INSTALLING A CLUSTER ON OPENSTACK WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.9, you can install a customized cluster on Red Hat OpenStack Platform (RHOSP). To customize the installation, modify parameters in the **install-config.yaml** before you install the cluster.

15.2.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You verified that OpenShift Container Platform 4.9 is compatible with your RHOSP version by using the [Supported platforms for OpenShift clusters](#) section. You can also compare platform support across different versions by viewing the [OpenShift Container Platform on RHOSP support matrix](#).
- You have a storage service installed in RHOSP, such as block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see [Optimizing storage](#).
- You have the metadata service enabled in RHOSP.

15.2.2. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

Table 15.1. Recommended resources for a default OpenShift Container Platform cluster on RHOSP

Resource	Value
Floating IP addresses	3
Ports	15
Routers	1
Subnets	1

Resource	Value
RAM	112 GB
vCPUs	28
Volume storage	275 GB
Instances	7
Security groups	3
Security group rules	60

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the **swiftoperator** role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

NOTE

By default, your security group and security group rule quotas might be low. If you encounter problems, run **openstack quota set --secgroups 3 --secgroup-rules 60 <project>** as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

15.2.2.1. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

15.2.2. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

15.2.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

15.2.4. Enabling Swift on RHOSP

Swift is operated by a user account with the **swiftoperator** role. Add the role to an account before you run the installation program.

IMPORTANT

If [the Red Hat OpenStack Platform \(RHOSP\) object storage service](#), commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

Prerequisites

- You have a RHOSP administrator account on the target environment.

- The Swift service is installed.
- On [Ceph RGW](#), the **account in url** option is enabled.

Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the **swiftoperator** role to the account that will access Swift:

```
$ openstack role add --user <user> --project <project> swiftoperator
```

Your RHOSP deployment can now use Swift for the image registry.

15.2.5. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Configure OpenStack's networking service to have DHCP agents forward instances' DNS queries

Procedure

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

```
$ openstack network list --long -c ID -c Name -c "Router Type"
```

Example output

ID	Name	Router Type
148a8023-62a7-4672-b018-003462f8d7dc	public_network	External

A network with an external router type appears in the network list. If at least one does not, see [Creating a default floating IP network](#) and [Creating a default provider network](#).

IMPORTANT

If the external network's CIDR range overlaps one of the default network ranges, you must change the matching network ranges in the **install-config.yaml** file before you start the installation process.

The default network ranges are:

Network	Range
machineNetwork	10.0.0.0/16
serviceNetwork	172.30.0.0/16
clusterNetwork	10.128.0.0/14

WARNING

If the installation program finds multiple networks with the same name, it sets one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

NOTE

If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see [Neutron trunk port](#).

15.2.6. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called **clouds.yaml**. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the **clouds.yaml** file:

- If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.

IMPORTANT

Remember to add a password to the **auth** field. You can also keep secrets in a [separate file](#) from **clouds.yaml**.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about **clouds.yaml**, see [Config files](#) in the RHOSP documentation.

```

clouds:
shiftstack:
auth:
auth_url: http://10.10.14.42:5000/v3
project_name: shiftstack
username: shiftstack_user
password: XXX
user_domain_name: Default
project_domain_name: Default
dev-env:
region_name: RegionOne
auth:
username: 'devuser'
password: XXX
project_name: 'devonly'
auth_url: 'https://10.10.14.22:5001/v2.0'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
 - a. Copy the certificate authority file to your machine.
 - b. Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

```

clouds:
shiftstack:
...
cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the **clouds.yaml** file in one of the following locations:
 - a. The value of the **OS_CLIENT_CONFIG_FILE** environment variable
 - b. The current directory
 - c. A Unix-specific user configuration directory, for example **~/.config/openstack/clouds.yaml**
 - d. A Unix-specific site configuration directory, for example **/etc/openstack/clouds.yaml**
The installation program searches for **clouds.yaml** in that order.

15.2.7. Setting cloud provider options

Optionally, you can edit the cloud provider configuration for your cluster. The cloud provider configuration controls how OpenShift Container Platform interacts with Red Hat OpenStack Platform (RHOSP).

For a complete list of cloud provider configuration parameters, see [the `cloud.conf` specification](#).

Procedure

- If you have not already generated manifest files for your cluster, generate them by running the following command:

```
$ openshift-install --dir <destination_directory> create manifests
```

- In a text editor, open the cloud-provider configuration manifest file. For example:

```
$ vi openshift/manifests/cloud-provider-config.yaml
```

- Modify the options based on [the `cloud.conf` specification](#).

Configuring Octavia for load balancing is a common case. For example:

```
#...
[LoadBalancer]
use-octavia=true ①
lb-provider = "amphora" ②
floating-network-id="d3deb660-4190-40a3-91f1-37326fe6ec4a" ③
#...
```

- ① This property enables Octavia integration.
- ② This property sets the Octavia provider that your load balancer uses. It accepts "**ovn**" or "**amphora**" as values. If you choose to use OVN, you must also set **lb-method** to **SOURCE_IP_PORT**.
- ③ This property is required if you want to use multiple external networks with your cluster. The cloud provider creates floating IP addresses on the network that is specified here.

IMPORTANT

Prior to saving your changes, verify that the file is structured correctly. Clusters might fail if properties are not placed in the appropriate section.

- Save the changes to the file and proceed with installation.

TIP

You can update your cloud provider configuration after you run the installer. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

After you save your changes, your cluster will take some time to reconfigure itself. The process is complete if none of your nodes have a **SchedulingDisabled** status.

15.2.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the [Infrastructure Provider](#) page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. From the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

15.2.9. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- Have the **imageContentSources** values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.

- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.
- Obtain service principal permissions at the subscription level.

Procedure

1. Create the **install-config.yaml** file.
 - a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir=<installation_directory> ①
```

- ① For **<installation_directory>**, specify the directory name to store the files that the installation program creates.

IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

- b. At the prompts, provide the configuration details for your cloud:

- i. Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **openstack** as the platform to target.
- iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.
- iv. Specify the floating IP address to use for external access to the OpenShift API.
- v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.
- vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.
- vii. Enter a name for your cluster. The name must be 14 or fewer characters long.
- viii. Paste the pull secret that you obtained from the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site.

2. In the **install-config.yaml** file, set the value of **platform.openstack.clusterOSImage** to the image location or name. For example:

```
platform:  
  openstack:  
    clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-  
    openstack.x86_64.qcow2.gz?  
    sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d
```

3. Edit the **install-config.yaml** file to provide the additional information that is required for an installation in a restricted network.

- a. Update the **pullSecret** value to contain the authentication information for your registry:

```
pullSecret: '{"auths": {"<mirror_host_name>:5000": {"auth": "<credentials>", "email":  
"you@example.com"}}}
```

For **<mirror_host_name>**, specify the registry domain name that you specified in the certificate for your mirror registry, and for **<credentials>**, specify the base64-encoded user name and password for your mirror registry.

- b. Add the **additionalTrustBundle** parameter and value.

```
additionalTrustBundle: |  
-----BEGIN CERTIFICATE-----  
  
ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ  
-----END CERTIFICATE-----
```

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

- c. Add the image content resources, which look like this excerpt:

```
imageContentSources:  
- mirrors:  
  - <mirror_host_name>:5000/<repo_name>/release  
    source: quay.example.com/openshift-release-dev/ocp-release  
- mirrors:  
  - <mirror_host_name>:5000/<repo_name>/release  
    source: registry.example.com/ocp/release
```

To complete these values, use the **imageContentSources** that you recorded during mirror registry creation.

4. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.
5. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

15.2.9.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

- If your cluster is on AWS, you added the **ec2.<region>.amazonaws.com**, **elasticloadbalancing.<region>.amazonaws.com**, and **s3.<region>.amazonaws.com** endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
  additionalTrustBundle: | 4
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
  ...
  ...
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**. If you use an MITM transparent proxy network that does not require additional CAs, you must not specify an **httpsProxy** value.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpsProxy** value.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, **y.com** matches **x.y.com**, but not **y.com**. Use `*` to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace to hold the additional CA certificates. If you provide **additionalTrustBundle** and at least one proxy setting, the **Proxy** object is configured to reference the **user-ca-bundle** config map in the **trustedCA** field. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges the contents specified for the **trustedCA** parameter with the RHCOS trust bundle. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE

The installation program does not support the proxy **readinessEndpoints** field.

- 2 Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

15.2.10. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster's platform. When you create the **install-config.yaml** installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the **install-config.yaml** file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

IMPORTANT

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

15.2.10.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 15.2. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>. <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}} .	String of lowercase letters, hyphens (-), and periods (.), such as dev . The string must be 14 characters or fewer long.

Parameter	Description	Values
platform	The configuration for the specific platform upon which to perform the installation: aws , baremetal , azure , openstack , ovirt , vsphere , or <code>{}</code> . For additional information about platform . <platform> parameters, consult the table for your specific platform that follows.	Object
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths": { "cloud.openshift.com": { "auth": "b3Blb=", "email": "you@example.com" }, "quay.io": { "auth": "b3Blb=", "email": "you@example.com" } } }</pre>

15.2.10.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 15.3. Network parameters

Parameter	Description	Values
networking	The configuration for the cluster network.	<p>Object</p>  <p>NOTE</p> <p>You cannot modify parameters specified by the networking object after installation.</p>

Parameter	Description	Values
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23 . If you specify multiple IP address blocks, the blocks must not overlap.	An array of objects. For example: <pre>networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</pre>
networking.clusterNetwork.cidr	Required if you use networking.clusterNetwork . An IP address block. An IPv4 network.	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{(32 - 23)} - 2$) pod IP addresses.	A subnet prefix. The default value is 23 .
networking.serviceNetwork	The IP address block for services. The default value is 172.30.0.0/16 . The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.	An array with an IP address block in CIDR format. For example: <pre>networking: serviceNetwork: - 172.30.0.0/16</pre>
networking.machineNetwork	The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.	An array of objects. For example: <pre>networking: machineNetwork: - cidr: 10.0.0.0/16</pre>

Parameter	Description	Values
networking.machineNetwork.cidr	Required if you use networking.machineNetwork . An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24 .	<p>An IP network block in CIDR notation. For example, 10.0.0.0/16.</p>  <p>NOTE Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.</p>

15.2.10.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 15.4. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String

Parameter	Description	Values
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String

Parameter	Description	Values
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	 IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws , azure , gcp , openstack , ovirt , vsphere , or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.	Mint, Passthrough, Manual , or an empty string ("").
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>NOTE</p> <p>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the <i>Cloud Credential Operator</i> entry in the <i>Red Hat Operators</i> reference content.</p>	false or true
imageContentSources	 <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.

Parameter	Description	Values
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.	Internal or External . The default value is External . Setting this field to Internal is not supported on non-cloud platforms.
sshKey	The SSH key or keys to authenticate access your cluster machines. 	One or more keys. For example: sshKey: <key1> <key2> <key3>

15.2.10.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

Table 15.5. Additional RHOSP parameters

Parameter	Description	Values
compute.platform.openstack.rootVolume.size	For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.	Integer, for example 30 .
compute.platform.openstack.rootVolume.type	For compute machines, the root volume's type.	String, for example performance .

Parameter	Description	Values
controlPlane.platform.openstack.rootVolume.size	For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.	Integer, for example 30 .
controlPlane.platform.openstack.rootVolume.type	For control plane machines, the root volume's type.	String, for example performance .
platform.openstack.cloud	The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file.	String, for example MyCloud .
platform.openstack.externalNetwork	The RHOSP external network name to be used for installation.	String, for example external .
platform.openstack.computeFlavor	The RHOSP flavor to use for control plane and compute machines. This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.	String, for example m1.xlarge .

15.2.10.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

Table 15.6. Optional RHOSP parameters

Parameter	Description	Values
-----------	-------------	--------

Parameter	Description	Values
compute.platform.openstack.additionalNetworkIDs	Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.	A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .
compute.platform.openstack.additionalSecurityGroupIDs	Additional security groups that are associated with compute machines.	A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7 .
compute.platform.openstack.zones	RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.	A list of strings. For example, ["zone-1", "zone-2"] .
compute.platform.openstack.rootVolume.zones	For compute machines, the availability zone to install root volumes on. If you do not set a value for this parameter, the installer selects the default availability zone.	A list of strings, for example ["zone-1", "zone-2"] .
controlPlane.platform.openstack.additionalNetworkIDs	Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.	A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .
controlPlane.platform.openstack.additionalSecurityGroupIDs	Additional security groups that are associated with control plane machines.	A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7 .

Parameter	Description	Values
controlPlane.platform.openstack.zones	RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.	A list of strings. For example, ["zone-1", "zone-2"] .
controlPlane.platform.openstack.rootVolume.zones	For control plane machines, the availability zone to install root volumes on. If you do not set this value, the installer selects the default availability zone.	A list of strings, for example ["zone-1", "zone-2"] .
platform.openstack.clusterOSImage	The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.	An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d . The value can also be the name of an existing Glance image, for example my-rhcos .

Parameter	Description	Values
platform.openstack.clusterOSImageProperties	<p>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image.</p> <p>You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi.</p> <p>You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</p>	A list of key-value string pairs. For example, <code>["hw_scsi_model": "virtio-scsi", "hw_disk_bus": "scsi"]</code> .
platform.openstack.defaultMachinePlatform	The default machine pool platform configuration.	<pre>{ "type": "ml.large", "rootVolume": { "size": 30, "type": "performance" } }</pre>
platform.openstack.ingressFloatingIP	An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.	An IP address, for example 128.0.0.1 .
platform.openstack.apiFloatingIP	An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property.	An IP address, for example 128.0.0.1 .
platform.openstack.externalDNS	IP addresses for external DNS servers that cluster instances use for DNS resolution.	A list of IP addresses as strings. For example, <code>["8.8.8", "192.168.1.12"]</code> .

Parameter	Description	Values
platform.openstack.machinesSubnet	<p>The UUID of a RHOSP subnet that the cluster's nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.</p> <p>The first item in networking.machineNetwork must match the value of machinesSubnet.</p> <p>If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.</p>	A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .

15.2.10.6. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet's GUID is passed as the value of **platform.openstack.machinesSubnet** in the **install-config.yaml** file.

This subnet is used as the cluster's primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the **platform.openstack.machinesSubnet** property to the subnet's UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by **platform.openstack.machinesSubnet** has DHCP enabled.
- The CIDR of **platform.openstack.machinesSubnet** matches the CIDR of **networking.machineNetwork**.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the **platform.openstack.machinesSubnet** subnet must be attached to a router that is connected to the **externalNetwork** network.
- If the **platform.openstack.machinesSubnet** value is set in the **install-config.yaml** file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the **platform.openstack.externalIDNS** property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network's CIDR block. To override these default values, set values for **platform.openstack.apiVIP** and **platform.openstack.ingressVIP** that are outside of the DHCP allocation pool.

15.2.10.7. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the **install-config.yaml** file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

**NOTE**

Be sure that your **install-config.yaml** file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

Prerequisites

- The RHOSP [Bare Metal service \(Ironic\)](#) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as [a RHOSP flavor](#).
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
- You created an **install-config.yaml** file as part of the OpenShift Container Platform installation process.

Procedure

1. In the **install-config.yaml** file, edit the flavors for machines:
 - a. If you want to use bare-metal control plane machines, change the value of **controlPlane.platform.openstack.type** to a bare metal flavor.
 - b. Change the value of **compute.platform.openstack.type** to a bare metal flavor.
 - c. If you want to deploy your machines on a pre-existing network, change the value of **platform.openstack.machinesSubnet** to the RHOSP subnet UUID of the network. Control plane and compute machines must use the same subnet.

An example bare metal **install-config.yaml** file

```
controlPlane:
  platform:
    openstack:
```

```

type: <bare_metal_control_plane_flavor> ①
...
compute:
- architecture: amd64
  hyperthreading: Enabled
  name: worker
  platform:
    openstack:
      type: <bare_metal_compute_flavor> ②
  replicas: 3
...
platform:
  openstack:
    machinesSubnet: <subnet_UUID> ③
...

```

- ① If you want to have bare-metal control plane machines, change this value to a bare metal flavor.
- ② Change this value to a bare metal flavor to use for compute machines.
- ③ If you want to use a pre-existing network, change this value to the UUID of the RHOSP subnet.

Use the updated **install-config.yaml** file to complete the installation process. The compute machines that are created during deployment use the flavor that you added to the file.

NOTE

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

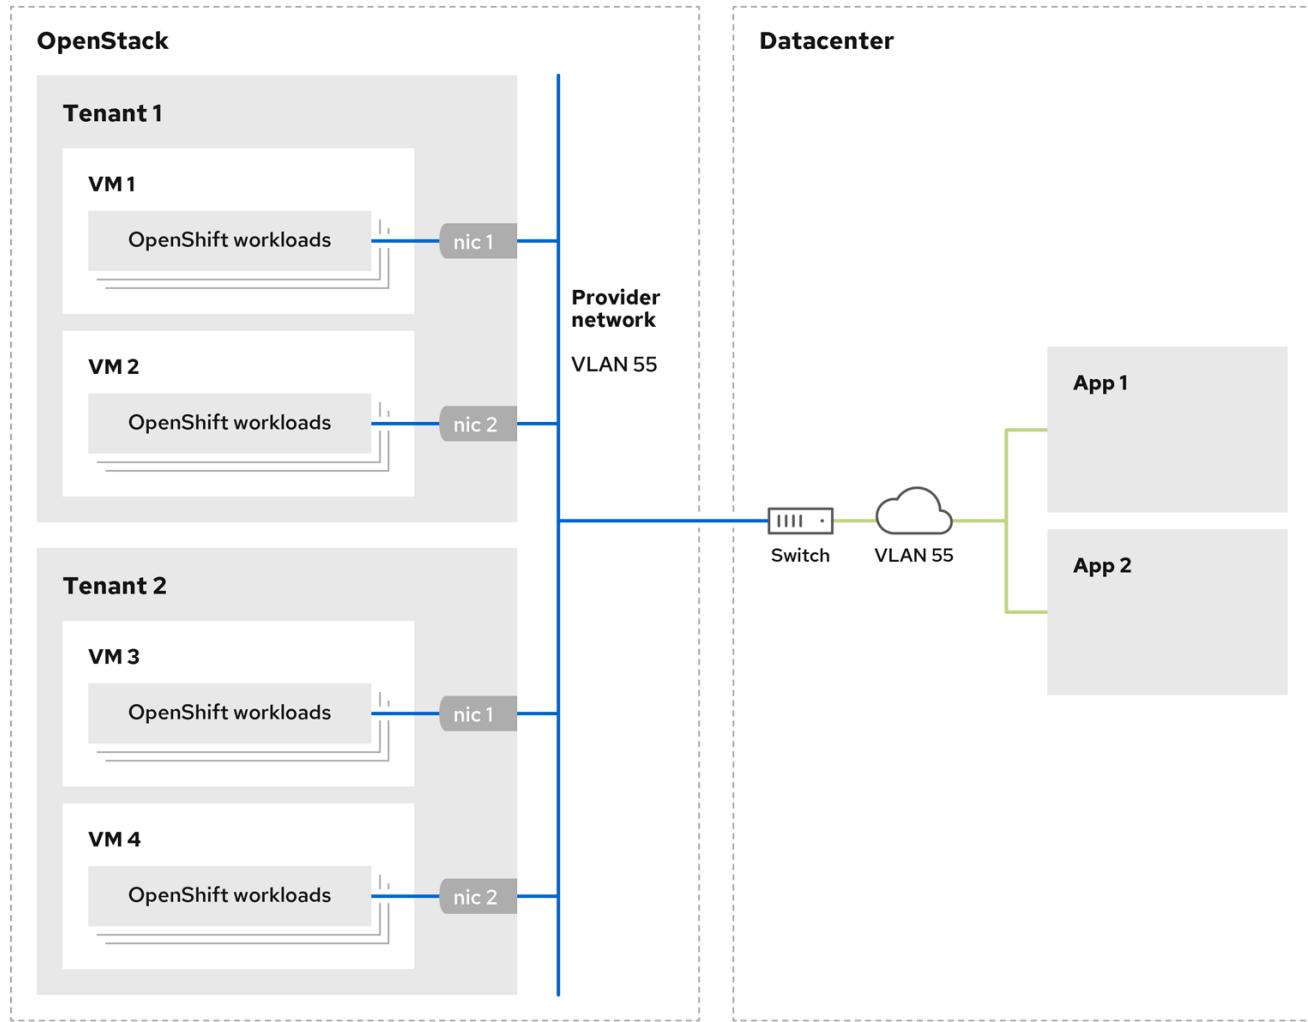

```
./openshift-install wait-for install-complete --log-level debug
```

15.2.10.8. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

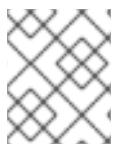

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:

170_OpenShift_0621

OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

NOTE

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in [the RHOSP documentation](#).

15.2.10.8.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The [RHOSP networking service \(Neutron\)](#) is enabled and accessible through the RHOSP networking API.
- The RHOSP networking service has the [port security and allowed address pairs extensions enabled](#).

- The provider network can be shared with other tenants.

TIP

Use the **openstack network create** command with the **--share** flag to create a network that can be shared.

- The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

TIP

To create a network for a project that is named "openshift," enter the following command

```
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command

```
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read [the provider networks documentation](#).

If the cluster is owned by the **admin** user, you must run the installer as that user to create ports on the network.

**IMPORTANT**

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is **169.254.169.254** by default.

Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```
$ openstack subnet create --dhcp --host-route
destination=169.254.169.254/32,gateway=192.0.2.2 ...
```

- Optional: To secure the network, create [role-based access control \(RBAC\)](#) rules that limit network access to a single project.

15.2.10.8.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network. .Prerequisites

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".

Procedure

1. In a text editor, open the **install-config.yaml** file.
2. Set the value of the **platform.openstack.apiVIP** property to the IP address for the API VIP.
3. Set the value of the **platform.openstack.ingressVIP** property to the IP address for the Ingress VIP.
4. Set the value of the **platform.openstack.machinesSubnet** property to the UUID of the provider network subnet.
5. Set the value of the **networking.machineNetwork.cidr** property to the CIDR block of the provider network subnet.

IMPORTANT

The **platform.openstack.apiVIP** and **platform.openstack.ingressVIP** properties must both be unassigned IP addresses from the **networking.machineNetwork.cidr** block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```
...
platform:
  openstack:
    apiVIP: 192.0.2.13
    ingressVIP: 192.0.2.23
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
    # ...
  networking:
    machineNetwork:
      - cidr: 192.0.2.0/24
```

WARNING

You cannot set the **platform.openstack.externalNetwork** or **platform.openstack.externalDNS** parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the **install-config.yaml** file to deploy the cluster on the provider network.

TIP

You can add additional networks, including provider networks, to the **platform.openstack.additionalNetworkIDs** list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).

15.2.10.9. Sample customized `install-config.yaml` file for RHOSP

This sample **`install-config.yaml`** demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

IMPORTANT

This sample file is provided for reference only. You must obtain your **`install-config.yaml`** file by using the installation program.

```
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
- name: worker
  platform:
    openstack:
      type: ml.large
    replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
  - cidr: 10.0.0.0/16
  serviceNetwork:
  - 172.30.0.0/16
networkType: OpenShiftSDN
platform:
  openstack:
    cloud: mycloud
    externalNetwork: external
    computeFlavor: m1.xlarge
    apiFloatingIP: 128.0.0.1
  fips: false
  pullSecret: '{"auths": ...}'
  sshKey: ssh-ed25519 AAAA...
```

15.2.11. Setting compute machine affinity

Optionally, you can set the affinity policy for compute machines during installation. The installer does not select an affinity policy for compute machines by default.

You can also create machine sets that use particular RHOSP server groups after installation.

NOTE

Control plane machines are created with a **soft-anti-affinity** policy.

TIP

You can learn more about [RHOSP instance scheduling and placement](#) in the RHOSP documentation.

Prerequisites

- Create the **install-config.yaml** file and complete any modifications to it.

Procedure

1. Using the RHOSP command-line interface, create a server group for your compute machines.
For example:

```
$ openstack \
    --os-compute-api-version=2.15 \
    server group create \
    --policy anti-affinity \
    my-openshift-worker-group
```

For more information, see the [server group create command documentation](#).

2. Change to the directory that contains the installation program and create the manifests:

```
$ ./openshift-install create manifests --dir=<installation_directory>
```

where:

installation_directory

Specifies the name of the directory that contains the **install-config.yaml** file for your cluster.

3. Open **manifests/99_openshift-cluster-api_worker-machineset-0.yaml**, the **MachineSet** definition file.
4. Add the property **serverGroupID** to the definition beneath the **spec.template.spec.providerSpec.value** property. For example:

```
apiVersion: machine.openshift.io/v1beta1
kind: MachineSet
metadata:
  labels:
    machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
    machine.openshift.io/cluster-api-machine-role: <node_role>
    machine.openshift.io/cluster-api-machine-type: <node_role>
  name: <infrastructure_ID>-<node_role>
  namespace: openshift-machine-api
spec:
  replicas: <number_of_replicas>
  selector:
    matchLabels:
      machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
      machine.openshift.io/cluster-api-machineset: <infrastructure_ID>-<node_role>
  template:
    metadata:
      labels:
```

```

machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
machine.openshift.io/cluster-api-machine-role: <node_role>
machine.openshift.io/cluster-api-machine-type: <node_role>
machine.openshift.io/cluster-api-machineset: <infrastructure_ID>-<node_role>
spec:
  providerSpec:
    value:
      apiVersion: openstackproviderconfig.openshift.io/v1alpha1
      cloudName: openstack
      cloudsSecret:
        name: openstack-cloud-credentials
        namespace: openshift-machine-api
      flavor: <nova_flavor>
      image: <glance_image_name_or_location>
      serverGroupID: aaaaaaaaa-bbbbcccc-dddd-eeeeeeeeeee ①
      kind: OpenstackProviderSpec
      networks:
        - filter: {}
          subnets:
            - filter:
                name: <subnet_name>
                tags: openshiftClusterID=<infrastructure_ID>
      securityGroups:
        - filter: {}
          name: <infrastructure_ID>-<node_role>
      serverMetadata:
        Name: <infrastructure_ID>-<node_role>
        openshiftClusterID: <infrastructure_ID>
      tags:
        - openshiftClusterID=<infrastructure_ID>
      trunk: true
      userDataSecret:
        name: <node_role>-user-data
      availabilityZone: <optional_openstack_availability_zone>

```

① Add the UUID of your server group here.

5. Optional: Back up the **manifests/99_openshift-cluster-api_worker-machineset-0.yaml** file. The installation program deletes the **manifests**/ directory when creating the cluster.

When you install the cluster, the installer uses the **MachineSet** definition that you modified to create compute machines within your RHOSP server group.

15.2.12. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the **~/.ssh/authorized_keys** list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **./openshift-install gather** command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
```

- 1 Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the **./openshift-install gather** command.

NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

Agent pid 31874

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> ①
```

- 1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

15.2.13. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

15.2.13.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

```
$ openstack floating ip create --description "API <cluster_name>.<base_domain>"<external_network>
```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

```
$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>"<external_network>
```

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

NOTE

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

- Add the FIPs to the **install-config.yaml** file as the values of the following parameters:

- **platform.openstack.ingressFloatingIP**
- **platform.openstack.apiFloatingIP**

If you use these values, you must also enter an external network as the value of the **platform.openstack.externalNetwork** parameter in the **install-config.yaml** file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

15.2.13.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the **install-config.yaml** file, do not define the following parameters:

- **platform.openstack.ingressFloatingIP**
- **platform.openstack.apiFloatingIP**

If you cannot provide an external network, you can also leave **platform.openstack.externalNetwork** blank. If you do not provide a value for **platform.openstack.externalNetwork**, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

15.2.14. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

- 1 Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir=<installation_directory> \ ①
--log-level=info ②
```

- 1 For **<installation_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

NOTE

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the **kubeadmin** user, display in your terminal.

Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-
Wt5AL"
INFO Time elapsed: 36m22s
```

NOTE

The cluster access and credential information also outputs to **<installation_directory>/openshift_install.log** when an installation succeeds.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

15.2.15. Verifying cluster status

You can verify your OpenShift Container Platform cluster's status during or after installation.

Procedure

1. In the cluster environment, export the administrator's kubeconfig file:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

```
$ oc get nodes
```

3. View your cluster's version:

```
$ oc get clusterversion
```

4. View your Operators' status:

```
$ oc get clusteroperator
```

5. View all running pods in the cluster:

```
$ oc get pods -A
```

15.2.16. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the

correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- ① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

15.2.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

15.2.18. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).

- If you need to enable external access to node ports, [configure ingress cluster traffic by using a node port](#).
- If you did not configure RHOSP to accept application traffic over floating IP addresses, [configure RHOSP access with floating IP addresses](#).

15.3. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR

In OpenShift Container Platform version 4.9, you can install a customized cluster on Red Hat OpenStack Platform (RHOSP) that uses Kuryr SDN. To customize the installation, modify parameters in the **install-config.yaml** before you install the cluster.

15.3.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You verified that OpenShift Container Platform 4.9 is compatible with your RHOSP version by using the [Supported platforms for OpenShift clusters](#) section. You can also compare platform support across different versions by viewing the [OpenShift Container Platform on RHOSP support matrix](#).
- You have a storage service installed in RHOSP, such as block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see [Optimizing storage](#).

15.3.2. About Kuryr SDN

Kuryr is a container network interface (CNI) plug-in solution that uses the [Neutron](#) and [Octavia](#) Red Hat OpenStack Platform (RHOSP) services to provide networking for pods and Services.

Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.

Kuryr components are installed as pods in OpenShift Container Platform using the **openshift-kuryr** namespace:

- **kuryr-controller** - a single service instance installed on a **master** node. This is modeled in OpenShift Container Platform as a **Deployment** object.
- **kuryr-cni** - a container installing and configuring Kuryr as a CNI driver on each OpenShift Container Platform node. This is modeled in OpenShift Container Platform as a **DaemonSet** object.

The Kuryr controller watches the OpenShift Container Platform API server for pod, service, and namespace create, update, and delete events. It maps the OpenShift Container Platform API calls to corresponding objects in Neutron and Octavia. This means that every network solution that implements the Neutron trunk port functionality can be used to back OpenShift Container Platform via Kuryr. This includes open source solutions such as Open vSwitch (OVS) and Open Virtual Network (OVN) as well as Neutron-compatible commercial SDNs.

Kuryr is recommended for OpenShift Container Platform deployments on encapsulated RHOSP tenant networks to avoid double encapsulation, such as running an encapsulated OpenShift Container Platform SDN over an RHOSP network.

If you use provider networks or tenant VLANs, you do not need to use Kuryr to avoid double encapsulation. The performance benefit is negligible. Depending on your configuration, though, using Kuryr to avoid having two overlays might still be beneficial.

Kuryr is not recommended in deployments where all of the following criteria are true:

- The RHOSP version is less than 16.
- The deployment uses UDP services, or a large number of TCP services on few hypervisors.

or

- The **ovn-octavia** Octavia driver is disabled.
- The deployment uses a large number of TCP services on few hypervisors.

15.3.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr

When using Kuryr SDN, the pods, services, namespaces, and network policies are using resources from the RHOSP quota; this increases the minimum requirements. Kuryr also has some additional requirements on top of what a default install requires.

Use the following quota to satisfy a default cluster's minimum requirements:

Table 15.7. Recommended resources for a default OpenShift Container Platform cluster on RHOSP with Kuryr

Resource	Value
Floating IP addresses	3 - plus the expected number of Services of LoadBalancer type
Ports	1500 - 1 needed per Pod
Routers	1
Subnets	250 - 1 needed per Namespace/Project
Networks	250 - 1 needed per Namespace/Project
RAM	112 GB
vCPUs	28
Volume storage	275 GB
Instances	7

Resource	Value
Security groups	250 - 1 needed per Service and per NetworkPolicy
Security group rules	1000
Load balancers	100 - 1 needed per Service
Load balancer listeners	500 - 1 needed per Service-exposed port
Load balancer pools	500 - 1 needed per Service-exposed port

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the **swiftoperator** role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

IMPORTANT

If you are using Red Hat OpenStack Platform (RHOSP) version 16 with the Amphora driver rather than the OVN Octavia driver, security groups are associated with service accounts instead of user projects.

Take the following notes into consideration when setting resources:

- The number of ports that are required is larger than the number of pods. Kuryr uses ports pools to have pre-created ports ready to be used by pods and speed up the pods' booting time.
- Each network policy is mapped into an RHOSP security group, and depending on the **NetworkPolicy** spec, one or more rules are added to the security group.
- Each service is mapped to an RHOSP load balancer. Consider this requirement when estimating the number of security groups required for the quota.
If you are using RHOSP version 15 or earlier, or the **ovn-octavia driver**, each load balancer has a security group with the user project.
- The quota does not account for load balancer resources (such as VM resources), but you must consider these resources when you decide the RHOSP deployment's size. The default installation will have more than 50 load balancers; the clusters must be able to accommodate them.
If you are using RHOSP version 16 with the OVN Octavia driver enabled, only one load balancer VM is generated; services are load balanced through OVN flows.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

To enable Kuryr SDN, your environment must meet the following requirements:

- Run RHOSP 13+.
- Have Overcloud with Octavia.
- Use Neutron Trunk ports extension.
- Use **openvswitch** firewall driver if ML2/OVS Neutron driver is used instead of **ovs-hybrid**.

15.3.3.1. Increasing quota

When using Kuryr SDN, you must increase quotas to satisfy the Red Hat OpenStack Platform (RHOSP) resources used by pods, services, namespaces, and network policies.

Procedure

- Increase the quotas for a project by running the following command:

```
$ sudo openstack quota set --secgroups 250 --secgroup-rules 1000 --ports 1500 --subnets 250 --networks 250 <project>
```

15.3.3.2. Configuring Neutron

Kuryr CNI leverages the Neutron Trunks extension to plug containers into the Red Hat OpenStack Platform (RHOSP) SDN, so you must use the **trunks** extension for Kuryr to properly work.

In addition, if you leverage the default ML2/OVS Neutron driver, the firewall must be set to **openvswitch** instead of **ovs_hybrid** so that security groups are enforced on trunk subports and Kuryr can properly handle network policies.

15.3.3.3. Configuring Octavia

Kuryr SDN uses Red Hat OpenStack Platform (RHOSP)'s Octavia LBaaS to implement OpenShift Container Platform services. Thus, you must install and configure Octavia components in RHOSP to use Kuryr SDN.

To enable Octavia, you must include the Octavia service during the installation of the RHOSP Overcloud, or upgrade the Octavia service if the Overcloud already exists. The following steps for enabling Octavia apply to both a clean install of the Overcloud or an Overcloud update.

NOTE

The following steps only capture the key pieces required during the [deployment of RHOSP](#) when dealing with Octavia. It is also important to note that [registry methods](#) vary.

This example uses the local registry method.

Procedure

1. If you are using the local registry, create a template to upload the images to the registry. For example:

```
(undercloud) $ openstack overcloud container image prepare \
```

```
-e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
--namespace=registry.access.redhat.com/rhosp13 \
--push-destination=<local-ip-from-undercloud.conf>:8787 \
--prefix=openstack- \
--tag-from-label {version}-{product-version} \
--output-env-file=/home/stack/templates/overcloud_images.yaml \
--output-images-file /home/stack/local_registry_images.yaml
```

- Verify that the **local_registry_images.yaml** file contains the Octavia images. For example:

```
...
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-api:13.0-43
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-health-manager:13.0-45
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-housekeeping:13.0-45
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-worker:13.0-44
  push_destination: <local-ip-from-undercloud.conf>:8787
```

NOTE

The Octavia container versions vary depending upon the specific RHOSP release installed.

- Pull the container images from **registry.redhat.io** to the Undercloud node:

```
(undercloud) $ sudo openstack overcloud container image upload \
--config-file /home/stack/local_registry_images.yaml \
--verbose
```

This may take some time depending on the speed of your network and Undercloud disk.

- Since an Octavia load balancer is used to access the OpenShift Container Platform API, you must increase their listeners' default timeouts for the connections. The default timeout is 50 seconds. Increase the timeout to 20 minutes by passing the following file to the Overcloud deploy command:

```
(undercloud) $ cat octavia_timeouts.yaml
parameter_defaults:
  OctaviaTimeoutClientData: 1200000
  OctaviaTimeoutMemberData: 1200000
```

NOTE

This is not needed for RHOSP 13.0.13+.

- Install or update your Overcloud environment with Octavia:

```
$ openstack overcloud deploy --templates \
-e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
-e octavia_timeouts.yaml
```

**NOTE**

This command only includes the files associated with Octavia; it varies based on your specific installation of RHOSP. See the RHOSP documentation for further information. For more information on customizing your Octavia installation, see [installation of Octavia using Director](#).

**NOTE**

When leveraging Kuryr SDN, the Overcloud installation requires the Neutron **trunk** extension. This is available by default on director deployments. Use the **openvswitch** firewall instead of the default **ovs-hybrid** when the Neutron backend is ML2/OVS. There is no need for modifications if the backend is ML2/OVN.

6. In RHOSP versions earlier than 13.0.13, add the project ID to the **octavia.conf** configuration file after you create the project.
 - To enforce network policies across services, like when traffic goes through the Octavia load balancer, you must ensure Octavia creates the Amphora VM security groups on the user project.
This change ensures that required load balancer security groups belong to that project, and that they can be updated to enforce services isolation.

**NOTE**

This task is unnecessary in RHOSP version 13.0.13 or later.

Octavia implements a new ACL API that restricts access to the load balancers VIP.

- a. Get the project ID

```
$ openstack project show <project>
```

Example output

Field	Value
description	
domain_id	default
enabled	True
id	PROJECT_ID
is_domain	False
name	*<project>*
parent_id	default
tags	[]

- b. Add the project ID to **octavia.conf** for the controllers.

- i. Source the **stackrc** file:

```
$ source stackrc # Undercloud credentials
```

- List the Overcloud controllers:

```
$ openstack server list
```

Example output

ID	Image	Flavor	Name	Status	Networks
6bef8e73-2ba5-4860-a0b1-3937f8ca7e01			controller-0	ACTIVE	
				ctlplane=192.168.24.8	overcloud-full controller
dd43173a-ab26-47f8-a2dc-8473b4a67ab9			compute-0	ACTIVE	
				ctlplane=192.168.24.6	overcloud-full compute

- SSH into the controller(s).

```
$ ssh heat-admin@192.168.24.8
```

- Edit the **octavia.conf** file to add the project into the list of projects where Amphora security groups are on the user's account.

```
# List of project IDs that are allowed to have Load balancer security groups
# belonging to them.
amp_secgrouAllowed_projects = PROJECT_ID
```

- Restart the Octavia worker so the new configuration loads.

```
controller-0$ sudo docker restart octavia_worker
```

NOTE

Depending on your RHOSP environment, Octavia might not support UDP listeners. If you use Kuryr SDN on RHOSP version 13.0.13 or earlier, UDP services are not supported. RHOSP version 16 or later support UDP.

15.3.3.3.1. The Octavia OVN Driver

Octavia supports multiple provider drivers through the Octavia API.

To see all available Octavia provider drivers, on a command line, enter:

```
$ openstack loadbalancer provider list
```

Example output

name	description
amphora	The Octavia Amphora driver.
octavia	Deprecated alias of the Octavia Amphora driver.
ovn	Octavia OVN driver.

Beginning with RHOSP version 16, the Octavia OVN provider driver (**ovn**) is supported on OpenShift Container Platform on RHOSP deployments.

ovn is an integration driver for the load balancing that Octavia and OVN provide. It supports basic load balancing capabilities, and is based on OpenFlow rules. The driver is automatically enabled in Octavia by Director on deployments that use OVN Neutron ML2.

The Amphora provider driver is the default driver. If **ovn** is enabled, however, Kuryr uses it.

If Kuryr uses **ovn** instead of Amphora, it offers the following benefits:

- Decreased resource requirements. Kuryr does not require a load balancer VM for each service.
- Reduced network latency.
- Increased service creation speed by using OpenFlow rules instead of a VM for each service.
- Distributed load balancing actions across all nodes instead of centralized on Amphora VMs.

You can [configure your cluster to use the Octavia OVN driver](#) after your RHOSP cloud is upgraded from version 13 to version 16.

15.3.3.4. Known limitations of installing with Kuryr

Using OpenShift Container Platform with Kuryr SDN has several known limitations.

RHOSP general limitations

Using OpenShift Container Platform with Kuryr SDN has several limitations that apply to all versions and environments:

- Service** objects with the **NodePort** type are not supported.
- Clusters that use the OVN Octavia provider driver support **Service** objects for which the **.spec.selector** property is unspecified only if the **.subsets.addresses** property of the **Endpoints** object includes the subnet of the nodes or pods.
- If the subnet on which machines are created is not connected to a router, or if the subnet is connected, but the router has no external gateway set, Kuryr cannot create floating IPs for **Service** objects with type **LoadBalancer**.

RHOSP version limitations

Using OpenShift Container Platform with Kuryr SDN has several limitations that depend on the RHOSP version.

- RHOSP versions before 16 use the default Octavia load balancer driver (Amphora). This driver requires that one Amphora load balancer VM is deployed per OpenShift Container Platform service. Creating too many services can cause you to run out of resources.
Deployments of later versions of RHOSP that have the OVN Octavia driver disabled also use the Amphora driver. They are subject to the same resource concerns as earlier versions of RHOSP.
- Octavia RHOSP versions before 13.0.13 do not support UDP listeners. Therefore, OpenShift Container Platform UDP services are not supported.
- Octavia RHOSP versions before 13.0.13 cannot listen to multiple protocols on the same port. Services that expose the same port to different protocols, like TCP and UDP, are not supported.

RHOSP environment limitations

There are limitations when using Kuryr SDN that depend on your deployment environment.

Because of Octavia's lack of support for the UDP protocol and multiple listeners, if the RHOSP version is earlier than 13.0.13, Kuryr forces pods to use TCP for DNS resolution.

In Go versions 1.12 and earlier, applications that are compiled with CGO support disabled use UDP only. In this case, the native Go resolver does not recognize the **use-vc** option in **resolv.conf**, which controls whether TCP is forced for DNS resolution. As a result, UDP is still used for DNS resolution, which fails.

To ensure that TCP forcing is allowed, compile applications either with the environment variable **CGO_ENABLED** set to **1**, i.e. **CGO_ENABLED=1**, or ensure that the variable is absent.

In Go versions 1.13 and later, TCP is used automatically if DNS resolution using UDP fails.

NOTE

musl-based containers, including Alpine-based containers, do not support the **use-vc** option.

RHOSP upgrade limitations

As a result of the RHOSP upgrade process, the Octavia API might be changed, and upgrades to the Amphora images that are used for load balancers might be required.

You can address API changes on an individual basis.

If the Amphora image is upgraded, the RHOSP operator can handle existing load balancer VMs in two ways:

- Upgrade each VM by triggering a [load balancer failover](#).
- Leave responsibility for upgrading the VMs to users.

If the operator takes the first option, there might be short downtimes during failovers.

If the operator takes the second option, the existing load balancers will not support upgraded Octavia API features, like UDP listeners. In this case, users must recreate their Services to use these features.

IMPORTANT

If OpenShift Container Platform detects a new Octavia version that supports UDP load balancing, it recreates the DNS service automatically. The service recreation ensures that the service default supports UDP load balancing.

The recreation causes the DNS service approximately one minute of downtime.

15.3.3.5. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

15.3.3.6. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

15.3.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

15.3.5. Enabling Swift on RHOSP

Swift is operated by a user account with the **swiftoperator** role. Add the role to an account before you run the installation program.

IMPORTANT

If [the Red Hat OpenStack Platform \(RHOSP\) object storage service](#), commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

Prerequisites

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
- On [Ceph RGW](#), the **account in url** option is enabled.

Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the **swiftoperator** role to the account that will access Swift:

```
$ openstack role add --user <user> --project <project> swiftoperator
```

Your RHOSP deployment can now use Swift for the image registry.

15.3.6. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- [Configure OpenStack's networking service to have DHCP agents forward instances' DNS queries](#)

Procedure

- Using the RHOSP CLI, verify the name and ID of the 'External' network:

```
$ openstack network list --long -c ID -c Name -c "Router Type"
```

Example output

ID	Name	Router Type
148a8023-62a7-4672-b018-003462f8d7dc	public_network	External

A network with an external router type appears in the network list. If at least one does not, see [Creating a default floating IP network](#) and [Creating a default provider network](#).

IMPORTANT

If the external network's CIDR range overlaps one of the default network ranges, you must change the matching network ranges in the **install-config.yaml** file before you start the installation process.

The default network ranges are:

Network	Range
machineNetwork	10.0.0.0/16
serviceNetwork	172.30.0.0/16
clusterNetwork	10.128.0.0/14

WARNING

If the installation program finds multiple networks with the same name, it sets one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

NOTE

If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see [Neutron trunk port](#).

15.3.7. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called **clouds.yaml**. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

- Create the **clouds.yaml** file:

- If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.

IMPORTANT

Remember to add a password to the **auth** field. You can also keep secrets in a separate file from **clouds.yaml**.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about **clouds.yaml**, see [Config files](#) in the RHOSP documentation.

```
clouds:
  shiftstack:
    auth:
      auth_url: http://10.10.14.42:5000/v3
      project_name: shiftstack
      username: shiftstack_user
      password: XXX
      user_domain_name: Default
      project_domain_name: Default
    dev-env:
      region_name: RegionOne
      auth:
        username: 'devuser'
        password: XXX
        project_name: 'devonly'
        auth_url: 'https://10.10.14.22:5001/v2.0'
```

- If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:

- Copy the certificate authority file to your machine.

- Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

```
clouds:
  shiftstack:
    ...
    cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

- Place the **clouds.yaml** file in one of the following locations:

- a. The value of the **OS_CLIENT_CONFIG_FILE** environment variable
- b. The current directory
- c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`
- d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`
The installation program searches for **clouds.yaml** in that order.

15.3.8. Setting cloud provider options

Optionally, you can edit the cloud provider configuration for your cluster. The cloud provider configuration controls how OpenShift Container Platform interacts with Red Hat OpenStack Platform (RHOSP).

For a complete list of cloud provider configuration parameters, see [the **cloud.conf** specification](#).

Procedure

1. If you have not already generated manifest files for your cluster, generate them by running the following command:

```
$ openshift-install --dir <destination_directory> create manifests
```

2. In a text editor, open the cloud-provider configuration manifest file. For example:

```
$ vi openshift/manifests/cloud-provider-config.yaml
```

3. Modify the options based on [the **cloud.conf** specification](#).

Configuring Octavia for load balancing is a common case. For example:

```
#...
[LoadBalancer]
use-octavia=true 1
lb-provider = "amphora" 2
floating-network-id="d3deb660-4190-40a3-91f1-37326fe6ec4a" 3
#...
```

- 1** This property enables Octavia integration.
- 2** This property sets the Octavia provider that your load balancer uses. It accepts "**ovn**" or "**amphora**" as values. If you choose to use OVN, you must also set **lb-method** to **SOURCE_IP_PORT**.
- 3** This property is required if you want to use multiple external networks with your cluster. The cloud provider creates floating IP addresses on the network that is specified here.

IMPORTANT

Prior to saving your changes, verify that the file is structured correctly. Clusters might fail if properties are not placed in the appropriate section.

- Save the changes to the file and proceed with installation.

TIP

You can update your cloud provider configuration after you run the installer. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

After you save your changes, your cluster will take some time to reconfigure itself. The process is complete if none of your nodes have a **SchedulingDisabled** status.

15.3.9. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

- Access the [Infrastructure Provider](#) page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
- Select your infrastructure provider.
- Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

- Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```
- From the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for

OpenShift Container Platform components.

15.3.10. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

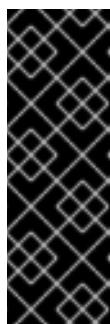

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- Have the **imageContentSources** values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.
- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.
- Obtain service principal permissions at the subscription level.

Procedure

1. Create the **install-config.yaml** file.
 - a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir=<installation_directory> ①
```
- ①** For **<installation_directory>**, specify the directory name to store the files that the installation program creates.

IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

- b. At the prompts, provide the configuration details for your cloud:

- i. Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **openstack** as the platform to target.
 - iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.
 - iv. Specify the floating IP address to use for external access to the OpenShift API.
 - v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.
 - vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.
 - vii. Enter a name for your cluster. The name must be 14 or fewer characters long.
 - viii. Paste the pull secret that you obtained from the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site.
2. In the **install-config.yaml** file, set the value of **platform.openstack.clusterOSImage** to the image location or name. For example:

```
platform:
  openstack:
    clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-
    openstack.x86_64.qcow2.gz?
    sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265
```

3. Edit the **install-config.yaml** file to provide the additional information that is required for an installation in a restricted network.

- a. Update the **pullSecret** value to contain the authentication information for your registry:

```
pullSecret: '{"auths": {"<mirror_host_name>:5000": {"auth": "<credentials>","email": "you@example.com"}}}
```

For **<mirror_host_name>**, specify the registry domain name that you specified in the certificate for your mirror registry, and for **<credentials>**, specify the base64-encoded user name and password for your mirror registry.

- b. Add the **additionalTrustBundle** parameter and value.

```
additionalTrustBundle: |
-----BEGIN CERTIFICATE-----
ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
-----END CERTIFICATE-----
```

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

- c. Add the image content resources, which look like this excerpt:

```
imageContentSources:
- mirrors:
  - <mirror_host_name>:5000/<repo_name>/release
```

```

source: quay.example.com/openshift-release-dev/ocp-release
- mirrors:
  - <mirror_host_name>:5000/<repo_name>/release
source: registry.example.com/ocp/release

```

To complete these values, use the **imageContentSources** that you recorded during mirror registry creation.

4. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the [Installation configuration parameters](#) section.
5. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

15.3.10.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

NOTE

Kuryr installations default to HTTP proxies.

Prerequisites

- For Kuryr installations on restricted networks that use the **Proxy** object, the proxy must be able to reply to the router that the cluster uses. To add a static route for the proxy configuration, from a command line as the root user, enter:

```
$ ip route add <cluster_network_cidr> via <installer_subnet_gateway>
```
- The restricted subnet must have a gateway that is defined and available to be linked to the **Router** resource that Kuryr creates.
- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the **ec2.<region>.amazonaws.com**, **elasticloadbalancing.<region>.amazonaws.com**, and **s3.<region>.amazonaws.com** endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

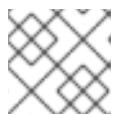

Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ①
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
  noProxy: example.com ③
  additionalTrustBundle: | ④
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
  ...
  ...
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpProxy** value.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpsProxy** value.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use `*` to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace to hold the additional CA certificates. If you provide **additionalTrustBundle** and at least one proxy setting, the **Proxy** object is configured to reference the **user-ca-bundle** config map in the **trustedCA** field. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges the contents specified for the **trustedCA** parameter with the RHCOS trust bundle. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by

an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE

The installation program does not support the proxy **readinessEndpoints** field.

- Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

15.3.11. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster's platform. When you create the **install-config.yaml** installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the **install-config.yaml** file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

IMPORTANT

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

15.3.11.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 15.8. Required parameters

Parameter	Description	Values
apiVersion	The API version for the Install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String

Parameter	Description	Values
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>.<baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}.{{.baseDomain}} .	String of lowercase letters, hyphens (-), and periods (.), such as dev . The string must be 14 characters or fewer long.
platform	The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere , or {} . For additional information about platform . <platform> parameters, consult the table for your specific platform that follows.	Object
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths":{ "cloud.openshift.com":{ "auth":"b3Blb=", "email":"you@example.com" }, "quay.io":{ "auth":"b3Blb=", "email":"you@example.com" } } }</pre>

15.3.11.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 15.9. Network parameters

Parameter	Description	Values
networking	The configuration for the cluster network.	<p>Object</p>  <p>NOTE</p> <p>You cannot modify parameters specified by the networking object after installation.</p>
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	<p>The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>	<p>An array of objects. For example:</p> <pre>networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</pre>
networking.clusterNetwork.cidr	<p>Required if you use networking.clusterNetwork. An IP address block.</p> <p>An IPv4 network.</p>	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{(32 - 23)} - 2$) pod IP addresses.	<p>A subnet prefix.</p> <p>The default value is 23.</p>

Parameter	Description	Values
networking.serviceNetwork	<p>The IP address block for services. The default value is 172.30.0.0/16.</p> <p>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</p>	An array with an IP address block in CIDR format. For example:
		<pre>networking: serviceNetwork: - 172.30.0.0/16</pre>
networking.machineNetwork	<p>The IP address blocks for machines.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>	An array of objects. For example:
		<pre>networking: machineNetwork: - cidr: 10.0.0.0/16</pre>
networking.machineNetwork.cidr	<p>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</p>	<p>An IP network block in CIDR notation.</p> <p>For example, 10.0.0.0/16.</p>  <p>NOTE</p> <p>Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.</p>

15.3.11.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 15.10. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.

Parameter	Description	Values
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere , or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.

Parameter	Description	Values
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	<p>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</p>  <p>NOTE</p> <p>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the <i>Cloud Credential Operator</i> entry in the <i>Red Hat Operators</i> reference content.</p>	Mint, Passthrough, Manual , or an empty string ("").
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	false or true

Parameter	Description	Values
imageContentSources	Sources and repositories for the release-image content.	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.	Internal or External . The default value is External . Setting this field to Internal is not supported on non-cloud platforms.
sshKey	The SSH key or keys to authenticate access your cluster machines. 	One or more keys. For example: sshKey: <key1> <key2> <key3>

15.3.11.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

Table 15.11. Additional RHOSP parameters

Parameter	Description	Values
compute.platform.openstack.rootVolume.size	For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.	Integer, for example 30 .

Parameter	Description	Values
compute.platform.openstack.rootVolume.type	For compute machines, the root volume's type.	String, for example performance .
controlPlane.platform.openstack.rootVolume.size	For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.	Integer, for example 30 .
controlPlane.platform.openstack.rootVolume.type	For control plane machines, the root volume's type.	String, for example performance .
platform.openstack.cloud	The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file.	String, for example MyCloud .
platform.openstack.externalNetwork	The RHOSP external network name to be used for installation.	String, for example external .
platform.openstack.computeFlavor	The RHOSP flavor to use for control plane and compute machines. This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.	String, for example m1.xlarge .

15.3.11.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

Table 15.12. Optional RHOSP parameters

Parameter	Description	Values
compute.platform.openstack.additionalNetworkIDs	Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.	A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .
compute.platform.openstack.additionalSecurityGroupIDs	Additional security groups that are associated with compute machines.	A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7 .
compute.platform.openstack.zones	<p>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured.</p> <p>On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</p>	A list of strings. For example, ["zone-1", "zone-2"] .
compute.platform.openstack.rootVolume.zones	For compute machines, the availability zone to install root volumes on. If you do not set a value for this parameter, the installer selects the default availability zone.	A list of strings, for example ["zone-1", "zone-2"] .
controlPlane.platform.openstack.additionalNetworkIDs	Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.	A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .
controlPlane.platform.openstack.additionalSecurityGroupIDs	Additional security groups that are associated with control plane machines.	A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7 .

Parameter	Description	Values
controlPlane.platform.openstack.zones	RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.	A list of strings. For example, ["zone-1", "zone-2"] .
controlPlane.platform.openstack.rootVolume.zones	For control plane machines, the availability zone to install root volumes on. If you do not set this value, the installer selects the default availability zone.	A list of strings, for example ["zone-1", "zone-2"] .
platform.openstack.clusterOSImage	The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.	An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d . The value can also be the name of an existing Glance image, for example my-rhcos .

Parameter	Description	Values
platform.openstack.clusterOSImageProperties	<p>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image.</p> <p>You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi.</p> <p>You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</p>	A list of key-value string pairs. For example, <code>["hw_scsi_model": "virtio-scsi", "hw_disk_bus": "scsi"]</code> .
platform.openstack.defaultMachinePlatform	The default machine pool platform configuration.	<pre>{ "type": "ml.large", "rootVolume": { "size": 30, "type": "performance" } }</pre>
platform.openstack.ingressFloatingIP	An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.	An IP address, for example 128.0.0.1 .
platform.openstack.apiFloatingIP	An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property.	An IP address, for example 128.0.0.1 .
platform.openstack.externalDNS	IP addresses for external DNS servers that cluster instances use for DNS resolution.	A list of IP addresses as strings. For example, <code>["8.8.8", "192.168.1.12"]</code> .

Parameter	Description	Values
platform.openstack.machinesSubnet	<p>The UUID of a RHOSP subnet that the cluster's nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.</p> <p>The first item in networking.machineNetwork must match the value of machinesSubnet.</p> <p>If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.</p>	A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .

15.3.11.6. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet's GUID is passed as the value of **platform.openstack.machinesSubnet** in the **install-config.yaml** file.

This subnet is used as the cluster's primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the **platform.openstack.machinesSubnet** property to the subnet's UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by **platform.openstack.machinesSubnet** has DHCP enabled.
- The CIDR of **platform.openstack.machinesSubnet** matches the CIDR of **networking.machineNetwork**.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the **platform.openstack.machinesSubnet** subnet must be attached to a router that is connected to the **externalNetwork** network.
- If the **platform.openstack.machinesSubnet** value is set in the **install-config.yaml** file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the **platform.openstack.externalIDNS** property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network's CIDR block. To override these default values, set values for **platform.openstack.apiVIP** and **platform.openstack.ingressVIP** that are outside of the DHCP allocation pool.

15.3.11.7. Sample customized `install-config.yaml` file for RHOSP with Kuryr

To deploy with Kuryr SDN instead of the default OpenShift SDN, you must modify the **install-config.yaml** file to include **Kuryr** as the desired **networking.networkType** and proceed with the default OpenShift Container Platform SDN installation steps. This sample **install-config.yaml** demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program.

```
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
- name: worker
  platform:
    openstack:
      type: ml.large
    replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
  - cidr: 10.0.0.0/16
  serviceNetwork:
  - 172.30.0.0/16 ①
networkType: Kuryr
platform:
  openstack:
    cloud: mycloud
    externalNetwork: external
    computeFlavor: m1.xlarge
    apiFloatingIP: 128.0.0.1
    trunkSupport: true ②
    octaviaSupport: true ③
  pullSecret: '{"auths": ...}'
  sshKey: ssh-ed25519 AAAA...
```

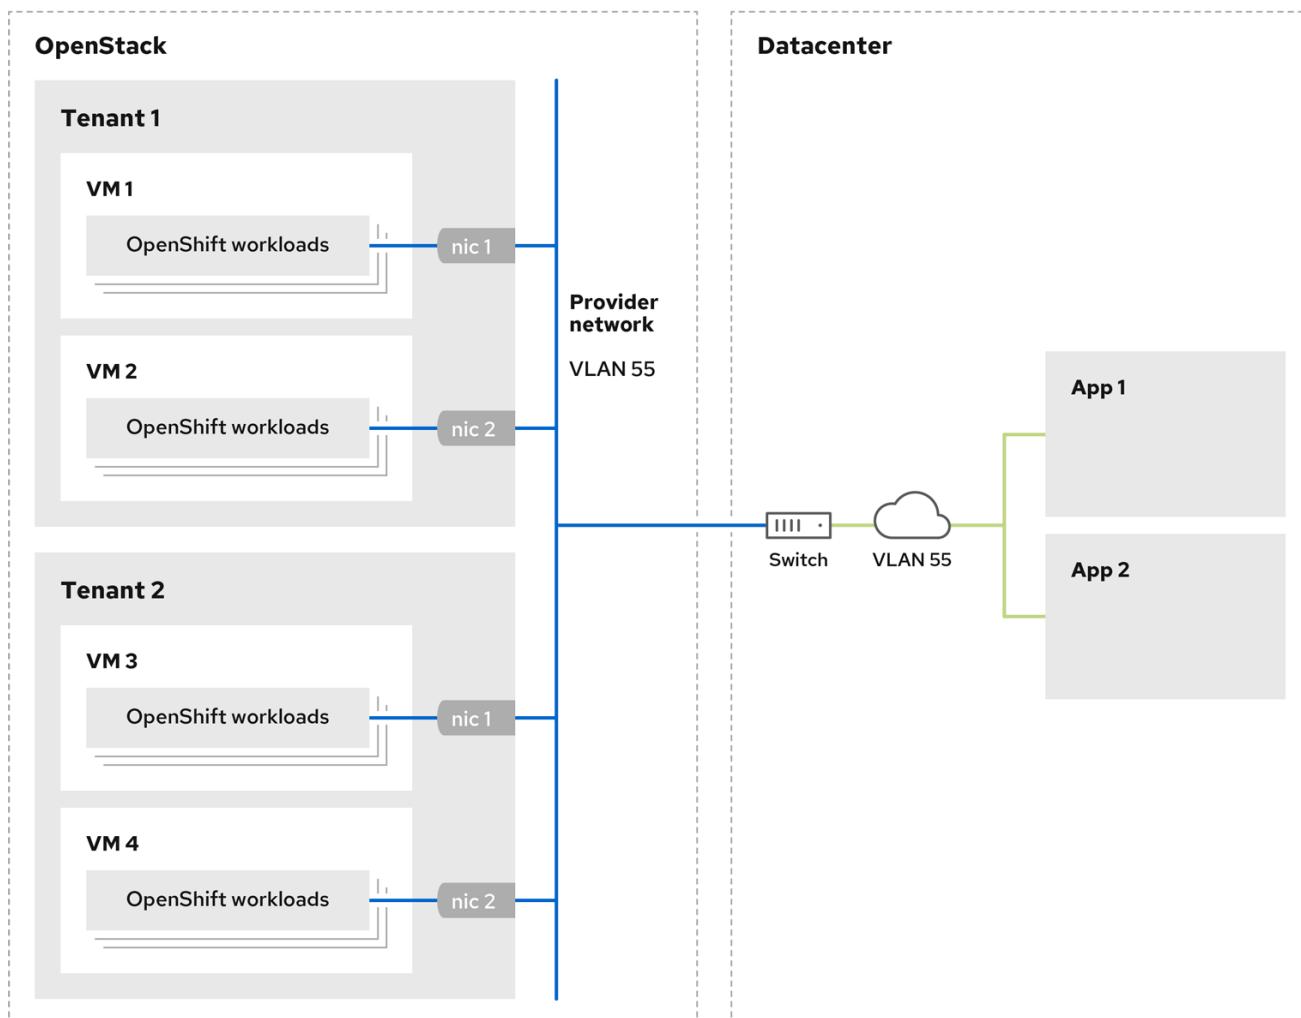

- 1 The Amphora Octavia driver creates two ports per load balancer. As a result, the service subnet that the installer creates is twice the size of the CIDR that is specified as the value of the `octaviaServiceSubnetSize` parameter.
- 2 Both `trunkSupport` and `octaviaSupport` are automatically discovered by the installer, so there is no need to set them. But if your environment does not meet both requirements, Kuryr SDN will not properly work. Trunks are needed to connect the pods to the RHOSP network and Octavia is required to create the OpenShift Container Platform services.

15.3.11.8. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:

170_OpenShift_0621

OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

NOTE

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in [the RHOSP documentation](#).

15.3.11.8.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The [RHOSP networking service \(Neutron\) is enabled](#) and accessible through the RHOSP networking API.
- The RHOSP networking service has the [port security and allowed address pairs extensions enabled](#).
- The provider network can be shared with other tenants.

TIP

Use the **openstack network create** command with the **--share** flag to create a network that can be shared.

- The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

TIP

To create a network for a project that is named "openshift," enter the following command

```
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command

```
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read [the provider networks documentation](#).

If the cluster is owned by the **admin** user, you must run the installer as that user to create ports on the network.

IMPORTANT

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is **169.254.169.254** by default.

Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```
$ openstack subnet create --dhcp --host-route
destination=169.254.169.254/32,gateway=192.0.2.2 ...
```

- Optional: To secure the network, create [role-based access control \(RBAC\)](#) rules that limit network access to a single project.

15.3.11.8.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network. .Prerequisites

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".

Procedure

- In a text editor, open the **install-config.yaml** file.
- Set the value of the **platform.openstack.apiVIP** property to the IP address for the API VIP.
- Set the value of the **platform.openstack.ingressVIP** property to the IP address for the Ingress VIP.
- Set the value of the **platform.openstack.machinesSubnet** property to the UUID of the provider network subnet.
- Set the value of the **networking.machineNetwork.cidr** property to the CIDR block of the provider network subnet.

IMPORTANT

The **platform.openstack.apiVIP** and **platform.openstack.ingressVIP** properties must both be unassigned IP addresses from the **networking.machineNetwork.cidr** block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```
...
platform:
  openstack:
    apiVIP: 192.0.2.13
    ingressVIP: 192.0.2.23
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
    # ...
networking:
  machineNetwork:
    - cidr: 192.0.2.0/24
```

**WARNING**

You cannot set the **platform.openstack.externalNetwork** or **platform.openstack.externalDNS** parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the **install-config.yaml** file to deploy the cluster on the provider network.

TIP

You can add additional networks, including provider networks, to the **platform.openstack.additionalNetworkIDs** list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).

15.3.11.9. Kuryr ports pools

A Kuryr ports pool maintains a number of ports on standby for pod creation.

Keeping ports on standby minimizes pod creation time. Without ports pools, Kuryr must explicitly request port creation or deletion whenever a pod is created or deleted.

The Neutron ports that Kuryr uses are created in subnets that are tied to namespaces. These pod ports are also added as subports to the primary port of OpenShift Container Platform cluster nodes.

Because Kuryr keeps each namespace in a separate subnet, a separate ports pool is maintained for each namespace-worker pair.

Prior to installing a cluster, you can set the following parameters in the **cluster-network-03-config.yml** manifest file to configure ports pool behavior:

- The **enablePortPoolsPrepopulation** parameter controls pool prepopulation, which forces Kuryr to add ports to the pool when it is created, such as when a new host is added, or a new namespace is created. The default value is **false**.
- The **poolMinPorts** parameter is the minimum number of free ports that are kept in the pool. The default value is **1**.
- The **poolMaxPorts** parameter is the maximum number of free ports that are kept in the pool. A value of **0** disables that upper bound. This is the default setting.
If your OpenStack port quota is low, or you have a limited number of IP addresses on the pod network, consider setting this option to ensure that unneeded ports are deleted.
- The **poolBatchPorts** parameter defines the maximum number of Neutron ports that can be created at once. The default value is **3**.

15.3.11.10. Adjusting Kuryr ports pools during installation

During installation, you can configure how Kuryr manages Red Hat OpenStack Platform (RHOSP) Neutron ports to control the speed and efficiency of pod creation.

Prerequisites

- Create and modify the **install-config.yaml** file.

Procedure

1. From a command line, create the manifest files:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

- ① For **<installation_directory>**, specify the name of the directory that contains the **install-config.yaml** file for your cluster.

2. Create a file that is named **cluster-network-03-config.yml** in the **<installation_directory>/manifests** directory:

```
$ touch <installation_directory>/manifests/cluster-network-03-config.yml ①
```

- ① For **<installation_directory>**, specify the directory name that contains the **manifests/** directory for your cluster.

After creating the file, several network configuration files are in the **manifests/** directory, as shown:

```
$ ls <installation_directory>/manifests/cluster-network-*
```

Example output

```
cluster-network-01-crd.yaml
cluster-network-02-config.yaml
cluster-network-03-config.yaml
```

3. Open the **cluster-network-03-config.yml** file in an editor, and enter a custom resource (CR) that describes the Cluster Network Operator configuration that you want:

```
$ oc edit networks.operator.openshift.io cluster
```

4. Edit the settings to meet your requirements. The following file is provided as an example:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  serviceNetwork:
  - 172.30.0.0/16
```

```

defaultNetwork:
  type: Kuryr
  kuryrConfig:
    enablePortPoolsPrepopulation: false 1
    poolMinPorts: 1 2
    poolBatchPorts: 3 3
    poolMaxPorts: 5 4
  openstackServiceNetwork: 172.30.0.0/15 5

```

- 1** Set the value of **enablePortPoolsPrepopulation** to **true** to make Kuryr create new Neutron ports after a namespace is created or a new node is added to the cluster. This setting raises the Neutron ports quota but can reduce the time that is required to spawn pods. The default value is **false**.
- 2** Kuryr creates new ports for a pool if the number of free ports in that pool is lower than the value of **poolMinPorts**. The default value is **1**.
- 3** **poolBatchPorts** controls the number of new ports that are created if the number of free ports is lower than the value of **poolMinPorts**. The default value is **3**.
- 4** If the number of free ports in a pool is higher than the value of **poolMaxPorts**, Kuryr deletes them until the number matches that value. Setting this value to **0** disables this upper bound, preventing pools from shrinking. The default value is **0**.
- 5** The **openStackServiceNetwork** parameter defines the CIDR range of the network from which IP addresses are allocated to RHOSP Octavia's LoadBalancers.

If this parameter is used with the Amphora driver, Octavia takes two IP addresses from this network for each load balancer: one for OpenShift and the other for VRRP connections. Because these IP addresses are managed by OpenShift Container Platform and Neutron respectively, they must come from different pools. Therefore, the value of **openStackServiceNetwork** must be at least twice the size of the value of **serviceNetwork**, and the value of **serviceNetwork** must overlap entirely with the range that is defined by **openStackServiceNetwork**.

The CNO verifies that VRRP IP addresses that are taken from the range that is defined by this parameter do not overlap with the range that is defined by the **serviceNetwork** parameter.

If this parameter is not set, the CNO uses an expanded value of **serviceNetwork** that is determined by decrementing the prefix size by 1.

5. Save the **cluster-network-03-config.yml** file, and exit the text editor.
6. Optional: Back up the **manifests/cluster-network-03-config.yml** file. The installation program deletes the **manifests/** directory while creating the cluster.

15.3.12. Setting compute machine affinity

Optionally, you can set the affinity policy for compute machines during installation. The installer does not select an affinity policy for compute machines by default.

You can also create machine sets that use particular RHOSP server groups after installation.

**NOTE**

Control plane machines are created with a **soft-anti-affinity** policy.

TIP

You can learn more about [RHOSP instance scheduling and placement](#) in the RHOSP documentation.

Prerequisites

- Create the **install-config.yaml** file and complete any modifications to it.

Procedure

1. Using the RHOSP command-line interface, create a server group for your compute machines. For example:

```
$ openstack \
--os-compute-api-version=2.15 \
server group create \
--policy anti-affinity \
my-openshift-worker-group
```

For more information, see the [server group create](#) command documentation.

2. Change to the directory that contains the installation program and create the manifests:

```
$ ./openshift-install create manifests --dir=<installation_directory>
```

where:

installation_directory

Specifies the name of the directory that contains the **install-config.yaml** file for your cluster.

3. Open **manifests/99_openshift-cluster-api_worker-machineset-0.yaml**, the **MachineSet** definition file.
4. Add the property **serverGroupID** to the definition beneath the **spec.template.spec.providerSpec.value** property. For example:

```
apiVersion: machine.openshift.io/v1beta1
kind: MachineSet
metadata:
labels:
  machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
  machine.openshift.io/cluster-api-machine-role: <node_role>
  machine.openshift.io/cluster-api-machine-type: <node_role>
name: <infrastructure_ID>-<node_role>
namespace: openshift-machine-api
spec:
replicas: <number_of_replicas>
selector:
matchLabels:
  machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
```

```

    machine.openshift.io/cluster-api-machineset: <infrastructure_ID>-<node_role>
template:
metadata:
labels:
    machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
    machine.openshift.io/cluster-api-machine-role: <node_role>
    machine.openshift.io/cluster-api-machine-type: <node_role>
    machine.openshift.io/cluster-api-machineset: <infrastructure_ID>-<node_role>
spec:
providerSpec:
value:
    apiVersion: openstackproviderconfig.openshift.io/v1alpha1
    cloudName: openstack
    cloudsSecret:
        name: openstack-cloud-credentials
        namespace: openshift-machine-api
    flavor: <nova_flavor>
    image: <glance_image_name_or_location>
    serverGroupID: aaaaaaaaa-bbbbcccc-dddd-eeeeeeeeeee ①
    kind: OpenstackProviderSpec
networks:
- filter: {}
  subnets:
- filter:
      name: <subnet_name>
      tags: openshiftClusterID=<infrastructure_ID>
securityGroups:
- filter: {}
  name: <infrastructure_ID>-<node_role>
serverMetadata:
  Name: <infrastructure_ID>-<node_role>
  openshiftClusterID: <infrastructure_ID>
tags:
- openshiftClusterID=<infrastructure_ID>
trunk: true
userDataSecret:
  name: <node_role>-user-data
availabilityZone: <optional_openstack_availability_zone>

```

- ① Add the UUID of your server group here.

5. Optional: Back up the **manifests/99_openshift-cluster-api_worker-machineset-0.yaml** file. The installation program deletes the **manifests/** directory when creating the cluster.

When you install the cluster, the installer uses the **MachineSet** definition that you modified to create compute machines within your RHOSP server group.

15.3.13. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the **~/.ssh/authorized_keys** list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **./openshift-install gather** command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the **./openshift-install gather** command.

NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> ①
```

- ① Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

15.3.14. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

15.3.14.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

Procedure

- Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

```
$ openstack floating ip create --description "API <cluster_name>.<base_domain>"<external_network>
```

- Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

```
$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>"<external_network>
```

- Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

NOTE

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

- Add the FIPs to the **install-config.yaml** file as the values of the following parameters:

- platform.openstack.ingressFloatingIP**
- platform.openstack.apiFloatingIP**

If you use these values, you must also enter an external network as the value of the **platform.openstack.externalNetwork** parameter in the **install-config.yaml** file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

15.3.14.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the **install-config.yaml** file, do not define the following parameters:

- platform.openstack.ingressFloatingIP**
- platform.openstack.apiFloatingIP**

If you cannot provide an external network, you can also leave **platform.openstack.externalNetwork** blank. If you do not provide a value for **platform.openstack.externalNetwork**, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

15.3.15. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the **create cluster** command of the installation program only once, during initial installation.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir=<installation_directory> \ ①
--log-level=info ②
```

- 1 For **<installation_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the **kubeadm** user, display in your terminal.

Example output

```
...
INFO Install complete!
```

```

INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-
Wt5AL"
INFO Time elapsed: 36m22s

```

**NOTE**

The cluster access and credential information also outputs to **<installation_directory>/openshift_install.log** when an installation succeeds.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

15.3.16. Verifying cluster status

You can verify your OpenShift Container Platform cluster's status during or after installation.

Procedure

1. In the cluster environment, export the administrator's kubeconfig file:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

```
$ oc get nodes
```

3. View your cluster's version:

```
$ oc get clusterversion
```

4. View your Operators' status:

```
$ oc get clusteroperator
```

5. View all running pods in the cluster:

```
$ oc get pods -A
```

15.3.17. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

15.3.18. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

15.3.19. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- If you need to enable external access to node ports, [configure ingress cluster traffic by using a node port](#).
- If you did not configure RHOSP to accept application traffic over floating IP addresses, [configure RHOSP access with floating IP addresses](#).

15.4. INSTALLING A CLUSTER ON OPENSTACK THAT SUPPORTS SR-IOV-CONNECTED COMPUTE MACHINES

In OpenShift Container Platform version 4.9, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that can use compute machines with single-root I/O virtualization (SR-IOV) technology.

15.4.1. Prerequisites

- Review details about the [OpenShift Container Platform installation and update](#) processes.
 - Verify that OpenShift Container Platform 4.9 is compatible with your RHOSP version by using the "Supported platforms for OpenShift clusters" section. You can also compare platform support across different versions by viewing the [OpenShift Container Platform on RHOSP support matrix](#).
- Verify that your network configuration does not rely on a provider network. Provider networks are not supported.
- Have a storage service installed in RHOSP, like block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see [Optimizing storage](#).
- Have metadata service enabled in RHOSP

15.4.2. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

Table 15.13. Recommended resources for a default OpenShift Container Platform cluster on RHOSP

Resource	Value
Floating IP addresses	3

Resource	Value
Ports	15
Routers	1
Subnets	1
RAM	112 GB
vCPUs	28
Volume storage	275 GB
Instances	7
Security groups	3
Security group rules	60

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the **swiftoperator** role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

NOTE

By default, your security group and security group rule quotas might be low. If you encounter problems, run **openstack quota set --secgroups 3 --secgroup-rules 60 <project>** as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

15.4.2.1. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota

- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

Additionally, for clusters that use single-root input/output virtualization (SR-IOV), RHOSP compute nodes require a flavor that supports [huge pages](#).

IMPORTANT

SR-IOV deployments often employ performance optimizations, such as dedicated or isolated CPUs. For maximum performance, configure your underlying RHOSP deployment to use these optimizations, and then run OpenShift Container Platform compute machines on the optimized infrastructure.

Additional resources

- For more information about configuring performant RHOSP compute nodes, see [Configuring Compute nodes for performance](#).

15.4.2.2. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

15.4.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

15.4.4. Enabling Swift on RHOSP

Swift is operated by a user account with the **swiftoperator** role. Add the role to an account before you run the installation program.

IMPORTANT

If [the Red Hat OpenStack Platform \(RHOSP\) object storage service](#), commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

Prerequisites

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
- On [Ceph RGW](#), the **account in url** option is enabled.

Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the **swiftoperator** role to the account that will access Swift:

```
$ openstack role add --user <user> --project <project> swiftoperator
```

Your RHOSP deployment can now use Swift for the image registry.

15.4.5. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- [Configure OpenStack's networking service to have DHCP agents forward instances' DNS queries](#)

Procedure

- Using the RHOSP CLI, verify the name and ID of the 'External' network:

```
$ openstack network list --long -c ID -c Name -c "Router Type"
```

Example output

ID	Name	Router Type
148a8023-62a7-4672-b018-003462f8d7dc	public_network	External

A network with an external router type appears in the network list. If at least one does not, see [Creating a default floating IP network](#) and [Creating a default provider network](#).

NOTE

If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see [Neutron trunk port](#).

15.4.6. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called **clouds.yaml**. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

- Create the **clouds.yaml** file:

- If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.

IMPORTANT

Remember to add a password to the **auth** field. You can also keep secrets in a separate file from **clouds.yaml**.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about **clouds.yaml**, see [Config files](#) in the RHOSP documentation.

```
clouds:
shiftstack:
auth:
  auth_url: http://10.10.14.42:5000/v3
  project_name: shiftstack
  username: shiftstack_user
  password: XXX
  user_domain_name: Default
  project_domain_name: Default
dev-env:
region_name: RegionOne
auth:
```

```
username: 'devuser'  
password: XXX  
project_name: 'devonly'  
auth_url: 'https://10.10.14.22:5001/v2.0'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:

- a. Copy the certificate authority file to your machine.
- b. Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

```
clouds:  
shiftstack:  
...  
cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the **clouds.yaml** file in one of the following locations:
 - a. The value of the **OS_CLIENT_CONFIG_FILE** environment variable
 - b. The current directory
 - c. A Unix-specific user configuration directory, for example **~/.config/openstack/clouds.yaml**
 - d. A Unix-specific site configuration directory, for example **/etc/openstack/clouds.yaml**
The installation program searches for **clouds.yaml** in that order.

15.4.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the [Infrastructure Provider](#) page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. From the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

15.4.8. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- Have the **imageContentSources** values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.
- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.
- Obtain service principal permissions at the subscription level.

Procedure

1. Create the **install-config.yaml** file.
 - a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir=<installation_directory> ①
```

- 1 For **<installation_directory>**, specify the directory name to store the files that the installation program creates.

IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

- b. At the prompts, provide the configuration details for your cloud:
 - i. Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Enter a descriptive name for your cluster.
- iii. Paste the pull secret that you obtained from the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site.

2. Edit the **install-config.yaml** file to provide the additional information that is required for an installation in a restricted network.

- a. Update the **pullSecret** value to contain the authentication information for your registry:

```
pullSecret: '{"auths": {"<mirror_host_name>:5000": {"auth": "<credentials>", "email": "you@example.com"}}}
```

For **<mirror_host_name>**, specify the registry domain name that you specified in the certificate for your mirror registry, and for **<credentials>**, specify the base64-encoded user name and password for your mirror registry.

- b. Add the **additionalTrustBundle** parameter and value.

```
additionalTrustBundle: |
-----BEGIN CERTIFICATE-----
ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
-----END CERTIFICATE-----
```

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

- c. Add the image content resources, which look like this excerpt:

```

imageContentSources:
- mirrors:
  - <mirror_host_name>:5000/<repo_name>/release
    source: quay.example.com/openshift-release-dev/ocp-release
- mirrors:
  - <mirror_host_name>:5000/<repo_name>/release
    source: registry.example.com/ocp/release

```

To complete these values, use the **imageContentSources** that you recorded during mirror registry creation.

3. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the [Installation configuration parameters](#) section.
4. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

15.4.8.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

- If your cluster is on AWS, you added the **ec2.<region>.amazonaws.com**, **elasticloadbalancing.<region>.amazonaws.com**, and **s3.<region>.amazonaws.com** endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
  additionalTrustBundle: | 4
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
...
```

- 1** A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpProxy** value.
- 2** A proxy URL to use for creating HTTPS connections outside the cluster. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpsProxy** value.
- 3** A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use `*` to bypass the proxy for all destinations.
- 4** If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace to hold the additional CA certificates. If you provide **additionalTrustBundle** and at least one proxy setting, the **Proxy** object is configured to reference the **user-ca-bundle** config map in the **trustedCA** field. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges the contents specified for the **trustedCA** parameter with the RHCOS trust bundle. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE

The installation program does not support the proxy **readinessEndpoints** field.

2. Save the file and reference it when installing OpenShift Container Platform.

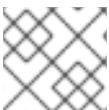

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

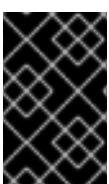

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

15.4.9. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster's platform. When you create the **install-config.yaml** installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the **install-config.yaml** file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the **install-config.yaml** file.

**IMPORTANT**

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

15.4.9.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 15.14. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>. <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .

Parameter	Description	Values
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}} .	String of lowercase letters, hyphens (-), and periods (.), such as dev .
platform	The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere, or {} . For additional information about platform . <platform> parameters, consult the table for your specific platform that follows.	Object
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths":{ "cloud.openshift.com":{ "auth":"b3Blb=", "email":"you@example.com" }, "quay.io":{ "auth":"b3Blb=", "email":"you@example.com" } } }</pre>

15.4.9.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 15.15. Network parameters

Parameter	Description	Values
-----------	-------------	--------

Parameter	Description	Values
networking	The configuration for the cluster network.	<p>Object</p>  <p>NOTE</p> <p>You cannot modify parameters specified by the networking object after installation.</p>
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	<p>The IP address blocks for pods.</p> <p>The default value is 10.128.0.0/14 with a host prefix of /23.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>	<p>An array of objects. For example:</p> <pre>networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</pre>
networking.clusterNetwork.cidr	<p>Required if you use networking.clusterNetwork. An IP address block.</p> <p>An IPv4 network.</p>	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	<p>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 ($2^{(32 - 23)} - 2$) pod IP addresses.</p>	<p>A subnet prefix.</p> <p>The default value is 23.</p>
networking.serviceNetwork	<p>The IP address block for services. The default value is 172.30.0.0/16.</p> <p>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</p>	<p>An array with an IP address block in CIDR format. For example:</p> <pre>networking: serviceNetwork: - 172.30.0.0/16</pre>
networking.machineNetwork	<p>The IP address blocks for machines.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>	<p>An array of objects. For example:</p> <pre>networking: machineNetwork: - cidr: 10.0.0.0/16</pre>

Parameter	Description	Values
networking.machineNetwork.cidr	Required if you use networking.machineNetwork . An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24 .	<p>An IP network block in CIDR notation. For example, 10.0.0.0/16.</p>  <p>NOTE Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.</p>

15.4.9.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 15.16. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String

Parameter	Description	Values
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String

Parameter	Description	Values
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	 IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws , azure , gcp , openstack , ovirt , vsphere , or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	<p>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</p>  <p>NOTE</p> <p>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the <i>Cloud Credential Operator</i> entry in the <i>Red Hat Operators</i> reference content.</p>	Mint, Passthrough, Manual , or an empty string ("").
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	false or true

Parameter	Description	Values
imageContentSources	Sources and repositories for the release-image content.	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.	Internal or External . The default value is External . Setting this field to Internal is not supported on non-cloud platforms.
sshKey	The SSH key or keys to authenticate access your cluster machines.  NOTE For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.	One or more keys. For example: sshKey: <key1> <key2> <key3>

15.4.9.4. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet's GUID is passed as the value of **platform.openstack.machinesSubnet** in the **install-config.yaml** file.

This subnet is used as the cluster's primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the **platform.openstack.machinesSubnet** property to the subnet's UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by **platform.openstack.machinesSubnet** has DHCP enabled.
- The CIDR of **platform.openstack.machinesSubnet** matches the CIDR of **networking.machineNetwork**.

- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the **platform.openstack.machinesSubnet** subnet must be attached to a router that is connected to the **externalNetwork** network.
- If the **platform.openstack.machinesSubnet** value is set in the **install-config.yaml** file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the **platform.openstack.externalDNS** property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

NOTE

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network's CIDR block. To override these default values, set values for **platform.openstack.apiVIP** and **platform.openstack.ingressVIP** that are outside of the DHCP allocation pool.

15.4.9.5. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the **inventory.yaml** file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

NOTE

Be sure that your **install-config.yaml** file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

Prerequisites

- The RHOSP [Bare Metal service \(Ironic\)](#) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a [RHOSP flavor](#).
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
- You created an **inventory.yaml** file as part of the OpenShift Container Platform installation process.

Procedure

1. In the **inventory.yaml** file, edit the flavors for machines:
 - a. If you want to use bare-metal control plane machines, change the value of **os_flavor_master** to a bare metal flavor.
 - b. Change the value of **os_flavor_worker** to a bare metal flavor.

An example bare metal **inventory.yaml** file

```
all:
  hosts:
    localhost:
      ansible_connection: local
      ansible_python_interpreter: "{{ansible_playbook_python}}"

      # User-provided values
      os_subnet_range: '10.0.0.0/16'
      os_flavor_master: 'my-bare-metal-flavor' 1
      os_flavor_worker: 'my-bare-metal-flavor' 2
      os_image_rhcos: 'rhcos'
      os_external_network: 'external'

  ...
```

- 1** If you want to have bare-metal control plane machines, change this value to a bare metal flavor.
- 2** Change this value to a bare metal flavor to use for compute machines.

Use the updated **inventory.yaml** file to complete the installation process. Machines that are created during deployment use the flavor that you added to the file.

NOTE

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
./openshift-install wait-for install-complete --log-level debug
```

15.4.9.6. Sample customized **install-config.yaml** file for RHOSP

This sample **install-config.yaml** demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

IMPORTANT

This sample file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program.

```
apiVersion: v1
baseDomain: example.com
```

```

controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
- name: worker
  platform:
    openstack:
      type: ml.large
  replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
  - cidr: 10.0.0.0/16
  serviceNetwork:
  - 172.30.0.0/16
  networkType: OpenShiftSDN
platform:
  openstack:
    cloud: mycloud
    externalNetwork: external
    computeFlavor: m1.xlarge
    apiFloatingIP: 128.0.0.1
fips: false
pullSecret: '{"auths": ...}'
sshKey: ssh-ed25519 AAAA...

```

15.4.10. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N " -f <path>/<file_name>
```

①

- 1 Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> ①
```

- ① Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

15.4.11. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

15.4.11.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

```
$ openstack floating ip create --description "API <cluster_name>.<base_domain>"<external_network>
```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

```
$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>"<external_network>
```

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

**NOTE**

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

- Add the FIPs to the **install-config.yaml** file as the values of the following parameters:

- **platform.openstack.ingressFloatingIP**
- **platform.openstack.apiFloatingIP**

If you use these values, you must also enter an external network as the value of the **platform.openstack.externalNetwork** parameter in the **install-config.yaml** file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

15.4.11.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the file, do not define the following

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

15.4.12. Creating SR-IOV networks for compute machines

If your Red Hat OpenStack Platform (RHOSP) deployment supports [single root I/O virtualization \(SR-IOV\)](#), you can provision SR-IOV networks that compute machines run on.

**NOTE**

The following instructions entail creating an external flat network and an external, VLAN-based network that can be attached to a compute machine. Depending on your RHOSP deployment, other network types might be required.

Prerequisites

- Your cluster supports SR-IOV.

NOTE

If you are unsure about what your cluster supports, review the OpenShift Container Platform SR-IOV hardware networks documentation.

- You created radio and uplink provider networks as part of your RHOSP deployment. The names **radio** and **uplink** are used in all example commands to represent these networks.

Procedure

1. On a command line, create a radio RHOSP network:

```
$ openstack network create radio --provider-physical-network radio --provider-network-type flat --external
```

2. Create an uplink RHOSP network:

```
$ openstack network create uplink --provider-physical-network uplink --provider-network-type vlan --external
```

3. Create a subnet for the radio network:

```
$ openstack subnet create --network radio --subnet-range <radio_network_subnet_range> radio
```

4. Create a subnet for the uplink network:

```
$ openstack subnet create --network uplink --subnet-range <uplink_network_subnet_range> uplink
```

15.4.13. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

Prerequisites

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir=<installation_directory> \ ①  
--log-level=info ②
```

- 1 For **<installation_directory>**, specify the
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

NOTE

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the **kubeadmin** user, display in your terminal.

Example output

```
...  
INFO Install complete!  
INFO To access the cluster as the system:admin user when using 'oc', run 'export  
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'  
INFO Access the OpenShift web-console here: https://console-openshift-  
console.apps.mycluster.example.com  
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-  
Wt5AL"  
INFO Time elapsed: 36m22s
```

NOTE

The cluster access and credential information also outputs to **<installation_directory>/openshift_install.log** when an installation succeeds.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

15.4.14. Verifying cluster status

You can verify your OpenShift Container Platform cluster's status during or after installation.

Procedure

1. In the cluster environment, export the administrator's kubeconfig file:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- 1 For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

```
$ oc get nodes
```

3. View your cluster's version:

```
$ oc get clusterversion
```

4. View your Operators' status:

```
$ oc get clusteroperator
```

5. View all running pods in the cluster:

```
$ oc get pods -A
```

15.4.15. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- 1 For <installation_directory>, specify the path to the directory that you stored the installation files in.

- 2 Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

The cluster is operational. Before you can add SR-IOV compute machines though, you must perform additional tasks.

15.4.16. Preparing a cluster that runs on RHOSP for SR-IOV

Before you use [single root I/O virtualization \(SR-IOV\)](#) on a cluster that runs on Red Hat OpenStack Platform (RHOSP), make the RHOSP metadata service mountable as a drive and enable the No-IOMMU Operator for the virtual function I/O (VFIO) driver.

15.4.16.1. Enabling the RHOSP metadata service as a mountable drive

You can apply a machine config to your machine pool that makes the Red Hat OpenStack Platform (RHOSP) metadata service available as a mountable drive.

The following machine config enables the display of RHOSP network UUIDs from within the SR-IOV Network Operator. This configuration simplifies the association of SR-IOV resources to cluster SR-IOV resources.

Procedure

- 1 Create a machine config file from the following template:

A mountable metadata service machine config file

```
kind: MachineConfig
apiVersion: machineconfiguration.openshift.io/v1
metadata:
  name: 20-mount-config ①
  labels:
    machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    systemd:
      units:
        - name: create-mountpoint-var-config.service
          enabled: true
          contents: |
            [Unit]
            Description=Create mountpoint /var/config
            Before=kubelet.service
```

```
[Service]
ExecStart=/bin/mkdir -p /var/config

[Install]
WantedBy=var-config.mount

- name: var-config.mount
  enabled: true
  contents: |
    [Unit]
    Before=local-fs.target
    [Mount]
    Where=/var/config
    What=/dev/disk/by-label/config-2
    [Install]
    WantedBy=local-fs.target
```

- 1 You can substitute a name of your choice.

- 2 From a command line, apply the machine config:

```
$ oc apply -f <machine_config_file_name>.yaml
```

15.4.16.2. Enabling the No-IOMMU feature for the RHOSP VFIO driver

You can apply a machine config to your machine pool that enables the No-IOMMU feature for the Red Hat OpenStack Platform (RHOSP) virtual function I/O (VFIO) driver. The RHOSP vfio-pci driver requires this feature.

Procedure

- 1 Create a machine config file from the following template:

A No-IOMMU VFIO machine config file

```
kind: MachineConfig
apiVersion: machineconfiguration.openshift.io/v1
metadata:
  name: 99-vfio-noiommu ①
  labels:
    machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      files:
        - path: /etc/modprobe.d/vfio-noiommu.conf
          mode: 0644
          contents:
            source:
              data::base64,b3B0aW9ucyB2ZmlvIGVuYWJsZV91bnNhZmVfbm9pb21tdV9tb2RIPTEK
```

- 1 You can substitute a name of your choice.

2. From a command line, apply the machine config:

```
$ oc apply -f <machine_config_file_name>.yaml
```

The cluster is installed and prepared for SR-IOV configuration. Complete the post-installation SR-IOV tasks that are listed in the "Next steps" section.

15.4.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

15.4.18. Next steps

- To complete SR-IOV configuration for your cluster:
 - [Install the Performance Addon Operator](#).
 - [Configure the Performance Addon Operator with huge pages support](#).
 - [Install the SR-IOV Operator](#).
 - [Configure your SR-IOV network device](#).
 - [Add an SR-IOV compute machine set](#).
- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- If you need to enable external access to node ports, [configure ingress cluster traffic by using a node port](#).
- If you did not configure RHOSP to accept application traffic over floating IP addresses, [configure RHOSP access with floating IP addresses](#).

15.5. INSTALLING A CLUSTER ON OPENSTACK ON YOUR OWN INFRASTRUCTURE

In OpenShift Container Platform version 4.9, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

15.5.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You verified that OpenShift Container Platform 4.9 is compatible with your RHOSP version by using the [Supported platforms for OpenShift clusters](#) section. You can also compare platform support across different versions by viewing the [OpenShift Container Platform on RHOSP support matrix](#).
- You have an RHOSP account where you want to install OpenShift Container Platform.
- On the machine from which you run the installation program, you have:
 - A single directory in which you can keep the files you create during the installation process
 - Python 3

15.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

15.5.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

Table 15.17. Recommended resources for a default OpenShift Container Platform cluster on RHOSP

Resource	Value
Floating IP addresses	3
Ports	15
Routers	1
Subnets	1
RAM	112 GB
vCPUs	28
Volume storage	275 GB
Instances	7
Security groups	3
Security group rules	60

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the **swiftoperator** role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

NOTE

By default, your security group and security group rule quotas might be low. If you encounter problems, run **openstack quota set --secgroups 3 --secgroup-rules 60 <project>** as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

15.5.3.1. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota

- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

15.5.3.2. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

15.5.4. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules' repositories and then download them.

**NOTE**

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

Prerequisites

- Python 3 is installed on your machine.

Procedure

1. On a command line, add the repositories:

a. Register with Red Hat Subscription Manager:

```
$ sudo subscription-manager register # If not done already
```

b. Pull the latest subscription data:

```
$ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
```

c. Disable the current repositories:

```
$ sudo subscription-manager repos --disable=* # If not done already
```

d. Add the required repositories:

■

```
$ sudo subscription-manager repos \
--enable=rhel-8-for-x86_64-baseos-rpms \
--enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
--enable=ansible-2.9-for-rhel-8-x86_64-rpms \
--enable=rhel-8-for-x86_64-appstream-rpms
```

2. Install the modules:

```
$ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr
```

3. Ensure that the **python** command points to **python3**:

```
$ sudo alternatives --set python /usr/bin/python3
```

15.5.5. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

Prerequisites

- The curl command-line tool is available on your machine.

Procedure

- To download the playbooks to your working directory, run the following script from a command line:

```
$ xargs -n 1 curl -O <<< '
  https://raw.githubusercontent.com/openshift/installer/release-
  4.9/upi/openstack/bootstrap.yaml
  https://raw.githubusercontent.com/openshift/installer/release-
  4.9/upi/openstack/common.yaml
  https://raw.githubusercontent.com/openshift/installer/release-
  4.9/upi/openstack/compute-nodes.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/control-
  plane.yaml
  https://raw.githubusercontent.com/openshift/installer/release-
  4.9/upi/openstack/inventory.yaml
  https://raw.githubusercontent.com/openshift/installer/release-
  4.9/upi/openstack/network.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/security-
  groups.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-
  bootstrap.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-
  compute-nodes.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-
  control-plane.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-
  load-balancers.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-
  network.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-
```

security-groups.yaml

[https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-containers.yaml'](https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-containers.yaml)

The playbooks are downloaded to your machine.

IMPORTANT

During the installation process, you can modify the playbooks to configure your deployment.

Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.

IMPORTANT

You must match any edits you make in the **bootstrap.yaml**, **compute-nodes.yaml**, **control-plane.yaml**, **network.yaml**, and **security-groups.yaml** files to the corresponding playbooks that are prefixed with **down-**. For example, edits to the **bootstrap.yaml** file must be reflected in the **down-bootstrap.yaml** file, too. If you do not edit both files, the supported cluster removal process will fail.

15.5.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the [Infrastructure Provider](#) page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. From the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

15.5.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> ①
```

- 1 Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

- View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

- Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

- Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```

1

- Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

15.5.8. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

Prerequisites

- The RHOSP CLI is installed.

Procedure

1. Log in to the Red Hat Customer Portal's [Product Downloads page](#).
2. Under **Version**, select the most recent release of OpenShift Container Platform 4.9 for Red Hat Enterprise Linux (RHEL) 8.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the *Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW)* .
4. Decompress the image.

NOTE

You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like **.gz** or **.tgz**. To find out if or how the file is compressed, in a command line, enter:

```
$ file <name_of_downloaded_file>
```

5. From the image that you downloaded, create an image that is named **rhcoss** in your cluster by using the RHOSP CLI:

```
$ openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-  
${RHCOS_VERSION}-openstack.qcow2 rhcos
```

IMPORTANT

Depending on your RHOSP environment, you might be able to upload the image in either [.raw](#) or [.qcow2](#) formats. If you use Ceph, you must use the [.raw](#) format.

**WARNING**

If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

After you upload the image to RHOSP, it is usable in the installation process.

15.5.9. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Configure OpenStack's networking service to have DHCP agents forward instances' DNS queries

Procedure

- Using the RHOSP CLI, verify the name and ID of the 'External' network:

```
$ openstack network list --long -c ID -c Name -c "Router Type"
```

Example output

ID	Name	Router Type
148a8023-62a7-4672-b018-003462f8d7dc	public_network	External

A network with an external router type appears in the network list. If at least one does not, see [Creating a default floating IP network](#) and [Creating a default provider network](#).

NOTE

If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see [Neutron trunk port](#).

15.5.10. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

15.5.10.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

```
$ openstack floating ip create --description "API <cluster_name>.<base_domain>"<external_network>
```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

```
$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>"<external_network>
```

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:

```
$ openstack floating ip create --description "bootstrap machine" <external_network>
```

4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>  
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

NOTE

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

5. Add the FIPs to the **inventory.yaml** file as the values of the following variables:

- **os_api_fip**
- **os_bootstrap_fip**
- **os_ingress_fip**

If you use these values, you must also enter an external network as the value of the **os_external_network** variable in the **inventory.yaml** file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

15.5.10.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the **inventory.yaml** file, do not define the following variables:

- **os_api_fip**
- **os_bootstrap_fip**
- **os_ingress_fip**

If you cannot provide an external network, you can also leave **os_external_network** blank. If you do not provide a value for **os_external_network**, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the **wait-for** command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

15.5.11. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called **clouds.yaml**. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the **clouds.yaml** file:

- If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.

IMPORTANT

Remember to add a password to the **auth** field. You can also keep secrets in a separate file from **clouds.yaml**.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about **clouds.yaml**, see [Config files](#) in the RHOSP documentation.

```

clouds:
shiftstack:
auth:
auth_url: http://10.10.14.42:5000/v3
project_name: shiftstack
username: shiftstack_user
password: XXX
user_domain_name: Default
project_domain_name: Default
dev-env:
region_name: RegionOne
auth:
username: 'devuser'
password: XXX
project_name: 'devonly'
auth_url: 'https://10.10.14.22:5001/v2.0'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
 - a. Copy the certificate authority file to your machine.
 - b. Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

```

clouds:
shiftstack:
...
cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the **clouds.yaml** file in one of the following locations:
 - a. The value of the **OS_CLIENT_CONFIG_FILE** environment variable
 - b. The current directory
 - c. A Unix-specific user configuration directory, for example **~/.config/openstack/clouds.yaml**
 - d. A Unix-specific site configuration directory, for example **/etc/openstack/clouds.yaml**
The installation program searches for **clouds.yaml** in that order.

15.5.12. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- Have the **imageContentSources** values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.
- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.
- Obtain service principal permissions at the subscription level.

Procedure

1. Create the **install-config.yaml** file.

- a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir=<installation_directory> ①
```

- ① For **<installation_directory>**, specify the directory name to store the files that the installation program creates.

IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

- b. At the prompts, provide the configuration details for your cloud:

- i. Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **openstack** as the platform to target.
- iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.
- iv. Specify the floating IP address to use for external access to the OpenShift API.

- v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.
 - vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.
 - vii. Enter a name for your cluster. The name must be 14 or fewer characters long.
 - viii. Paste the pull secret that you obtained from the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site.
2. In the **install-config.yaml** file, set the value of **platform.openstack.clusterOSImage** to the image location or name. For example:

```
platform:
  openstack:
    clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-
    openstack.x86_64.qcow2.gz?
    sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d
```

3. Edit the **install-config.yaml** file to provide the additional information that is required for an installation in a restricted network.
- Update the **pullSecret** value to contain the authentication information for your registry:

```
pullSecret: '{"auths":{"<mirror_host_name>:5000": {"auth": "<credentials>", "email": "you@example.com"}}}
```

For **<mirror_host_name>**, specify the registry domain name that you specified in the certificate for your mirror registry, and for **<credentials>**, specify the base64-encoded user name and password for your mirror registry.

- Add the **additionalTrustBundle** parameter and value.

```
additionalTrustBundle: |
-----BEGIN CERTIFICATE-----
ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
-----END CERTIFICATE-----
```

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

- Add the image content resources, which look like this excerpt:

```
imageContentSources:
- mirrors:
  - <mirror_host_name>:5000/<repo_name>/release
  source: quay.example.com/openshift-release-dev/ocp-release
- mirrors:
  - <mirror_host_name>:5000/<repo_name>/release
  source: registry.example.com/ocp/release
```

To complete these values, use the **imageContentSources** that you recorded during mirror registry creation.

4. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.
5. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file **install-config.yaml** in the directory that you specified.

15.5.13. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster's platform. When you create the **install-config.yaml** installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the **install-config.yaml** file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

IMPORTANT

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

15.5.13.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 15.18. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String

Parameter	Description	Values
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>. <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}} .	String of lowercase letters, hyphens (-), and periods (.), such as dev . The string must be 14 characters or fewer long.
platform	The configuration for the specific platform upon which to perform the installation: aws , baremetal , azure , openstack , ovirt , vsphere , or {} . For additional information about platform . <platform> parameters, consult the table for your specific platform that follows.	Object
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths": { "cloud.openshift.com": { "auth": "b3Blb=", "email": "you@example.com" }, "quay.io": { "auth": "b3Blb=", "email": "you@example.com" } } }</pre>

15.5.13.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 15.19. Network parameters

Parameter	Description	Values
networking	The configuration for the cluster network.	<p>Object</p>  <p>NOTE</p> <p>You cannot modify parameters specified by the networking object after installation.</p>
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	<p>The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>	<p>An array of objects. For example:</p> <pre>networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</pre>
networking.clusterNetwork.cidr	<p>Required if you use networking.clusterNetwork. An IP address block.</p> <p>An IPv4 network.</p>	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{(32 - 23)} - 2$) pod IP addresses.	<p>A subnet prefix.</p> <p>The default value is 23.</p>

Parameter	Description	Values
networking.serviceNetwork	<p>The IP address block for services. The default value is 172.30.0.0/16.</p> <p>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</p>	An array with an IP address block in CIDR format. For example:
		<pre>networking: serviceNetwork: - 172.30.0.0/16</pre>
networking.machineNetwork	<p>The IP address blocks for machines.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>	An array of objects. For example:
		<pre>networking: machineNetwork: - cidr: 10.0.0.0/16</pre>
networking.machineNetwork.cidr	<p>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</p>	<p>An IP network block in CIDR notation.</p> <p>For example, 10.0.0.0/16.</p>  <p>NOTE</p> <p>Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.</p>

15.5.13.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 15.20. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.

Parameter	Description	Values
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	 IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere , or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.

Parameter	Description	Values
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	<p>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</p>  <p>NOTE</p> <p>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the <i>Cloud Credential Operator</i> entry in the <i>Red Hat Operators</i> reference content.</p>	Mint, Passthrough, Manual , or an empty string ("").
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	false or true

Parameter	Description	Values
imageContentSources	Sources and repositories for the release-image content.	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.	<p>Internal or External. The default value is External.</p> <p>Setting this field to Internal is not supported on non-cloud platforms.</p>
sshKey	The SSH key or keys to authenticate access your cluster machines.	<p>One or more keys. For example:</p> <pre>sshKey: <key1> <key2> <key3></pre>

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

15.5.13.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

Table 15.21. Additional RHOSP parameters

Parameter	Description	Values
compute.platform.openstack.rootVolume.size	For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.	Integer, for example 30 .

Parameter	Description	Values
compute.platform.openstack.rootVolume.type	For compute machines, the root volume's type.	String, for example performance .
controlPlane.platform.openstack.rootVolume.size	For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.	Integer, for example 30 .
controlPlane.platform.openstack.rootVolume.type	For control plane machines, the root volume's type.	String, for example performance .
platform.openstack.cloud	The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file.	String, for example MyCloud .
platform.openstack.externalNetwork	The RHOSP external network name to be used for installation.	String, for example external .
platform.openstack.computeFlavor	The RHOSP flavor to use for control plane and compute machines. This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.	String, for example m1.xlarge .

15.5.13.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

Table 15.22. Optional RHOSP parameters

Parameter	Description	Values
compute.platform.openstack.additionalNetworkIDs	Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.	A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .
compute.platform.openstack.additionalSecurityGroupIDs	Additional security groups that are associated with compute machines.	A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7 .
compute.platform.openstack.zones	RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.	A list of strings. For example, ["zone-1", "zone-2"] .
compute.platform.openstack.rootVolume.zones	For compute machines, the availability zone to install root volumes on. If you do not set a value for this parameter, the installer selects the default availability zone.	A list of strings, for example ["zone-1", "zone-2"] .
controlPlane.platform.openstack.additionalNetworkIDs	Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.	A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .
controlPlane.platform.openstack.additionalSecurityGroupIDs	Additional security groups that are associated with control plane machines.	A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7 .

Parameter	Description	Values
controlPlane.platform.openstack.zones	RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.	A list of strings. For example, ["zone-1", "zone-2"] .
controlPlane.platform.openstack.rootVolume.zones	For control plane machines, the availability zone to install root volumes on. If you do not set this value, the installer selects the default availability zone.	A list of strings, for example ["zone-1", "zone-2"] .
platform.openstack.clusterOSImage	The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.	An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d . The value can also be the name of an existing Glance image, for example my-rhcos .

Parameter	Description	Values
platform.openstack.clusterOSImageProperties	<p>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image.</p> <p>You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi.</p> <p>You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</p>	A list of key-value string pairs. For example, <code>["hw_scsi_model": "virtio-scsi", "hw_disk_bus": "scsi"]</code> .
platform.openstack.defaultMachinePlatform	The default machine pool platform configuration.	<pre>{ "type": "ml.large", "rootVolume": { "size": 30, "type": "performance" } }</pre>
platform.openstack.ingressFloatingIP	An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.	An IP address, for example 128.0.0.1 .
platform.openstack.apiFloatingIP	An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property.	An IP address, for example 128.0.0.1 .
platform.openstack.externalDNS	IP addresses for external DNS servers that cluster instances use for DNS resolution.	A list of IP addresses as strings. For example, <code>["8.8.8", "192.168.1.12"]</code> .

Parameter	Description	Values
platform.openstack.machinesSubnet	<p>The UUID of a RHOSP subnet that the cluster's nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.</p> <p>The first item in networking.machineNetwork must match the value of machinesSubnet.</p> <p>If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.</p>	A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .

15.5.13.6. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet's GUID is passed as the value of **platform.openstack.machinesSubnet** in the **install-config.yaml** file.

This subnet is used as the cluster's primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the **platform.openstack.machinesSubnet** property to the subnet's UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by **platform.openstack.machinesSubnet** has DHCP enabled.
- The CIDR of **platform.openstack.machinesSubnet** matches the CIDR of **networking.machineNetwork**.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the **platform.openstack.machinesSubnet** subnet must be attached to a router that is connected to the **externalNetwork** network.
- If the **platform.openstack.machinesSubnet** value is set in the **install-config.yaml** file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the **platform.openstack.externalIDNS** property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network's CIDR block. To override these default values, set values for **platform.openstack.apiVIP** and **platform.openstack.ingressVIP** that are outside of the DHCP allocation pool.

15.5.13.7. Sample customized `install-config.yaml` file for RHOSP

This sample **install-config.yaml** demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program.

```
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
- name: worker
  platform:
    openstack:
      type: ml.large
    replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
  - cidr: 10.0.0.0/16
  serviceNetwork:
  - 172.30.0.0/16
networkType: OpenShiftSDN
platform:
  openstack:
    cloud: mycloud
    externalNetwork: external
    computeFlavor: m1.xlarge
    apiFloatingIP: 128.0.0.1
  tips: false
  pullSecret: '{"auths": ...}'
  sshKey: ssh-ed25519 AAAA...
```

15.5.13.8. Setting a custom subnet for machines

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.

Prerequisites

- You have the **install-config.yaml** file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains **install-config.yaml**.
2. From that directory, either run a script to edit the **install-config.yaml** file or update the file manually:
 - To set the value by using a script, run:

```
$ python -c '
import yaml;
path = "install-config.yaml";
data = yaml.safe_load(open(path));
data["networking"]["machineNetwork"] = [{"cidr": "192.168.0.0/18"}]; ①
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

① Insert a value that matches your intended Neutron subnet, e.g. **192.0.2.0/24**.

- To set the value manually, open the file and set the value of **networking.machineCIDR** to something that matches your intended Neutron subnet.

15.5.13.9. Emptying compute machine pools

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

Prerequisites

- You have the **install-config.yaml** file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains **install-config.yaml**.
2. From that directory, either run a script to edit the **install-config.yaml** file or update the file manually:
 - To set the value by using a script, run:

```
$ python -c '
import yaml;
path = "install-config.yaml";
data = yaml.safe_load(open(path));
data["compute"][0]["replicas"] = 0;
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

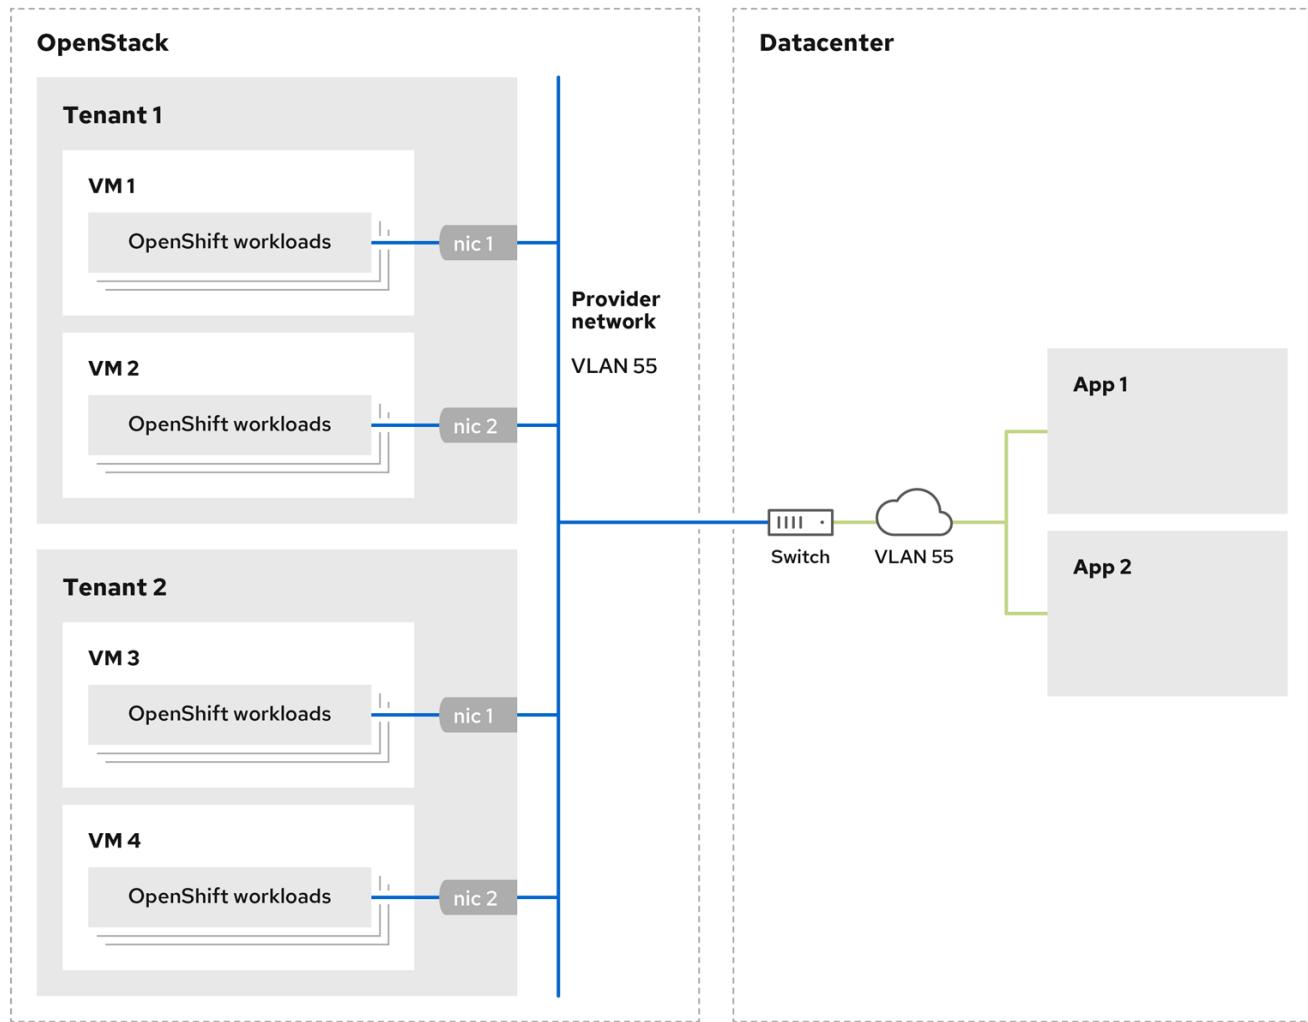

- To set the value manually, open the file and set the value of **compute.<first entry>.replicas** to **0**.

15.5.13.10. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:

170_OpenShift_0621

OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

NOTE

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in [the RHOSP documentation](#).

15.5.13.10.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The [RHOSP networking service \(Neutron\)](#) is enabled and accessible through the RHOSP networking API.
- The RHOSP networking service has the [port security and allowed address pairs extensions enabled](#).
- The provider network can be shared with other tenants.

TIP

Use the **openstack network create** command with the **--share** flag to create a network that can be shared.

- The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

TIP

To create a network for a project that is named "openshift," enter the following command

```
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command

```
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read [the provider networks documentation](#).

If the cluster is owned by the **admin** user, you must run the installer as that user to create ports on the network.

IMPORTANT

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is **169.254.169.254** by default.

Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```
$ openstack subnet create --dhcp --host-route
destination=169.254.169.254/32,gateway=192.0.2.2 ...
```

- Optional: To secure the network, create [role-based access control \(RBAC\)](#) rules that limit network access to a single project.

15.5.13.10.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network. .Prerequisites

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".

Procedure

1. In a text editor, open the **install-config.yaml** file.
2. Set the value of the **platform.openstack.apiVIP** property to the IP address for the API VIP.
3. Set the value of the **platform.openstack.ingressVIP** property to the IP address for the Ingress VIP.
4. Set the value of the **platform.openstack.machinesSubnet** property to the UUID of the provider network subnet.
5. Set the value of the **networking.machineNetwork.cidr** property to the CIDR block of the provider network subnet.

IMPORTANT

The **platform.openstack.apiVIP** and **platform.openstack.ingressVIP** properties must both be unassigned IP addresses from the **networking.machineNetwork.cidr** block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```
...
platform:
  openstack:
    apiVIP: 192.0.2.13
    ingressVIP: 192.0.2.23
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
    # ...
networking:
  machineNetwork:
    - cidr: 192.0.2.0/24
```

WARNING

You cannot set the **platform.openstack.externalNetwork** or **platform.openstack.externalDNS** parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the **install-config.yaml** file to deploy the cluster on the provider network.

TIP

You can add additional networks, including provider networks, to the **platform.openstack.additionalNetworkIDs** list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).

15.5.14. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the **install-config.yaml** installation configuration file.

Procedure

- 1 Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

Example output

```
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift
```

- 1 For **<installation_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

```
$ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

3. Check that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:

- a. Open the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file.
- b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
- c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory> ①
```

- 1 For **<installation_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation_directory>/auth** directory:

5. Export the metadata file's **infraID** key as an environment variable:

```
$ export INFRA_ID=$(jq -r .infraID metadata.json)
```

TIP

Extract the **infraID** key from **metadata.json** and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

15.5.15. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

Prerequisites

- You have the bootstrap Ignition file that the installer program generates, **bootstrap.ign**.
- The infrastructure ID from the installer's metadata file is set as an environment variable (**\$INFRA_ID**).
 - If the variable is not set, see [Creating the Kubernetes manifest and Ignition config files](#)
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
 - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

Procedure

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the hostname and, if available, CA certificate file when it runs:

```
import base64
import json
import os

with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

    files = ignition['storage'].get('files', [])

    infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
    hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap\n').decode().strip()
    files.append(
    {
        'path': '/etc/hostname',
        'mode': 420,
        'contents': {
            'source': 'data:text/plain;charset=utf-8;base64,' + hostname_b64
        }
    })

    ca_cert_path = os.environ.get('OS_CACERT', "")
    if ca_cert_path:
        with open(ca_cert_path, 'r') as f:
            ca_cert = f.read().encode()
            ca_cert_b64 = base64.standard_b64encode(ca_cert).decode().strip()

        files.append(
        {
            'path': '/opt/openshift/tls/cloud-ca-cert.pem',
            'mode': 420,
        })
    
```

```

    'contents': {
        'source': 'data:text/plain;charset=utf-8;base64,' + ca_cert_b64
    }
})

ignition['storage']['files'] = files;

with open('bootstrap.ign', 'w') as f:
    json.dump(ignition, f)

```

- Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

```
$ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign <image_name>
```

- Get the image's details:

```
$ openstack image show <image_name>
```

Make a note of the **file** value; it follows the pattern **v2/images/<image_ID>/file**.

NOTE

Verify that the image you created is active.

- Retrieve the image service's public address:

```
$ openstack catalog show image
```

- Combine the public address with the image **file** value and save the result as the storage location. The location follows the pattern **<image_service_public_URL>/v2/images/<image_ID>/file**.

- Generate an auth token and save the token ID:

```
$ openstack token issue -c id -f value
```

- Insert the following content into a file called **\$INFRA_ID-bootstrap-ignition.json** and edit the placeholders to match your own values:

```
{
    "ignition": {
        "config": {
            "merge": [
                {
                    "source": "<storage_url>", ①
                    "httpHeaders": [
                        {
                            "name": "X-Auth-Token", ②
                            "value": "<token_ID>" ③
                        }
                    ]
                }
            ],
            "security": {
                "tls": {

```

```

    "certificateAuthorities": [
      "source": "data:text/plain;charset=utf-8;base64,<base64_encoded_certificate>" 4
    ],
  },
  "version": "3.2.0"
}

```

- 1** Replace the value of **ignition.config.merge.source** with the bootstrap Ignition file storage URL.
- 2** Set **name** in **httpHeaders** to "**X-Auth-Token**".
- 3** Set **value** in **httpHeaders** to your token's ID.
- 4** If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.

WARNING

The bootstrap Ignition file contains sensitive information, like **clouds.yaml** credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

15.5.16. Creating control plane Ignition config files on RHOSP

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.

NOTE

As with the bootstrap Ignition configuration, you must explicitly define a hostname for each control plane machine.

Prerequisites

- The infrastructure ID from the installation program's metadata file is set as an environment variable (**\$INFRA_ID**).
 - If the variable is not set, see "Creating the Kubernetes manifest and Ignition config files".

Procedure

- On a command line, run the following Python script:

```
$ for index in $(seq 0 2); do
    MASTER_HOSTNAME="$INFRA_ID-master-$index\n"
    python -c "import base64, json, sys;
    ignition = json.load(sys.stdin);
    storage = ignition.get('storage', {});
    files = storage.get('files', []);
    files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {'source':
    'data:text/plain;charset=utf-8;base64,' +
    base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(), 'verification': {}},
    'filesystem': 'root'});
    storage['files'] = files;
    ignition['storage'] = storage
    json.dump(ignition, sys.stdout)" <master.ign >"$INFRA_ID-master-$index-ignition.json"
done
```

You now have three control plane Ignition files: **<INFRA_ID>-master-0-ignition.json**, **<INFRA_ID>-master-1-ignition.json**, and **<INFRA_ID>-master-2-ignition.json**.

15.5.17. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.

Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

Procedure

1. Optional: Add an external network value to the **inventory.yaml** playbook:

Example external network value in the **inventory.yaml** Ansible playbook

```
...
# The public network providing connectivity to the cluster. If not
# provided, the cluster external connectivity must be provided in another
# way.

# Required for os_api_fip, os_ingress_fip, os_bootstrap_fip.
os_external_network: 'external'
...
```

IMPORTANT

If you did not provide a value for **os_external_network** in the **inventory.yaml** file, you must ensure that VMs can access Glance and an external connection yourself.

2. Optional: Add external network and floating IP (FIP) address values to the **inventory.yaml** playbook:

Example FIP values in the **inventory.yaml** Ansible playbook

```
...
# OpenShift API floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the Control Plane to
# serve the OpenShift API.
os_api_fip: '203.0.113.23'

# OpenShift Ingress floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the worker nodes to serve
# the applications.
os_ingress_fip: '203.0.113.19'

# If this value is non-empty, the corresponding floating IP will be
# attached to the bootstrap machine. This is needed for collecting logs
# in case of install failure.
os_bootstrap_fip: '203.0.113.20'
```

IMPORTANT

If you do not define values for **os_api_fip** and **os_ingress_fip**, you must perform post-installation network configuration.

If you do not define a value for **os_bootstrap_fip**, the installer cannot download debugging information from failed installations.

See "Enabling access to the environment" for more information.

3. On a command line, create security groups by running the **security-groups.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml security-groups.yaml
```

4. On a command line, create a network, subnet, and router by running the **network.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml network.yaml
```

5. Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:

```
$ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2>
"--$INFRA_ID-nodes"
```

Optionally, you can use the **inventory.yaml** file that you created to customize your installation. For example, you can deploy a cluster that uses bare metal machines.

15.5.17.1. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the **inventory.yaml** file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

NOTE

Be sure that your **install-config.yaml** file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

Prerequisites

- The RHOSP Bare Metal service (Ironic) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a RHOSP flavor.
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
- You created an **inventory.yaml** file as part of the OpenShift Container Platform installation process.

Procedure

1. In the **inventory.yaml** file, edit the flavors for machines:
 - a. If you want to use bare-metal control plane machines, change the value of **os_flavor_master** to a bare metal flavor.
 - b. Change the value of **os_flavor_worker** to a bare metal flavor.

An example bare metal **inventory.yaml** file

```

all:
  hosts:
    localhost:
      ansible_connection: local
      ansible_python_interpreter: "{{ansible_playbook_python}}"

      # User-provided values
      os_subnet_range: '10.0.0.0/16'
      os_flavor_master: 'my-bare-metal-flavor' 1
      os_flavor_worker: 'my-bare-metal-flavor' 2
      os_image_rhcos: 'rhcos'
      os_external_network: 'external'

...
  
```

1 If you want to have bare-metal control plane machines, change this value to a bare metal flavor.

- 2** Change this value to a bare metal flavor to use for compute machines.

Use the updated **inventory.yaml** file to complete the installation process. Machines that are created during deployment use the flavor that you added to the file.

NOTE

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
./openshift-install wait-for install-complete --log-level debug
```

15.5.18. Creating the bootstrap machine on RHOSP

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **bootstrap.yaml** Ansible playbooks are in a common directory.
- The **metadata.json** file that the installation program created is in the same directory as the Ansible playbooks.

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the **bootstrap.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml bootstrap.yaml
```
3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:

```
$ openstack console log show "$INFRA_ID-bootstrap"
```

15.5.19. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".

- You downloaded the playbooks in "Downloading the installation playbooks".
- The infrastructure ID from the installation program's metadata file is set as an environment variable (**\$INFRA_ID**).
- The **inventory.yaml**, **common.yaml**, and **control-plane.yaml** Ansible playbooks are in a common directory.
- You have the three Ignition files that were created in "Creating control plane Ignition config files".

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. If the control plane Ignition config files aren't already in your working directory, copy them into it.
3. On a command line, run the **control-plane.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml control-plane.yaml
```
4. Run the following command to monitor the bootstrapping process:

```
$ openshift-install wait-for bootstrap-complete
```

You will see messages that confirm that the control plane machines are running and have joined the cluster:

```
INFO API v1.22.1 up  
INFO Waiting up to 30m0s for bootstrapping to complete...  
...  
INFO It is now safe to remove the bootstrap resources
```

15.5.20. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- 1** For <installation_directory>, specify the path to the directory that you stored the installation files in.

- Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

15.5.21. Deleting bootstrap resources from RHOSP

Delete the bootstrap resources that you no longer need.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **down-bootstrap.yaml** Ansible playbooks are in a common directory.
- The control plane machines are running.
 - If you do not know the status of the machines, see "Verifying cluster status".

Procedure

- On a command line, change the working directory to the location of the playbooks.
- On a command line, run the **down-bootstrap.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml down-bootstrap.yaml
```

The bootstrap port, server, and floating IP address are deleted.

WARNING

If you did not disable the bootstrap Ignition file URL earlier, do so now.

15.5.22. Creating compute machines on RHOSP

After standing up the control plane, create compute machines. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **compute-nodes.yaml** Ansible playbooks are in a common directory.
- The **metadata.json** file that the installation program created is in the same directory as the Ansible playbooks.
- The control plane is active.

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the playbook:

```
$ ansible-playbook -i inventory.yaml compute-nodes.yaml
```

Next steps

- Approve the certificate signing requests for the machines.

15.5.23. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.22.1
master-1	Ready	master	63m	v1.22.1
master-2	Ready	master	64m	v1.22.1

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

- Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-8b2br	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
csr-8vnps	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
...			

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

- If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approvers** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	Pending
csr-c57lv	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	Pending
...			

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs oc adm certificate approve
```

- After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	73m	v1.22.1
master-1	Ready	master	73m	v1.22.1
master-2	Ready	master	74m	v1.22.1
worker-0	Ready	worker	11m	v1.22.1
worker-1	Ready	worker	11m	v1.22.1

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

15.5.24. Verifying a successful installation

Verify that the OpenShift Container Platform installation is complete.

Prerequisites

- You have the installation program (**openshift-install**)

Procedure

- On a command line, enter:

```
$ openshift-install --log-level debug wait-for install-complete
```

The program outputs the console URL, as well as the administrator's login information.

15.5.25. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

15.5.26. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- If you need to enable external access to node ports, [configure ingress cluster traffic by using a node port](#).
- If you did not configure RHOSP to accept application traffic over floating IP addresses, [configure RHOSP access with floating IP addresses](#).

15.6. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR ON YOUR OWN INFRASTRUCTURE

In OpenShift Container Platform version 4.9, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

15.6.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You verified that OpenShift Container Platform 4.9 is compatible with your RHOSP version by using the [Supported platforms for OpenShift clusters](#) section. You can also compare platform support across different versions by viewing the [OpenShift Container Platform on RHOSP support matrix](#).
- You have an RHOSP account where you want to install OpenShift Container Platform.
- On the machine from which you run the installation program, you have:
 - A single directory in which you can keep the files you create during the installation process
 - Python 3

15.6.2. About Kuryr SDN

Kuryr is a container network interface (CNI) plug-in solution that uses the [Neutron](#) and [Octavia](#) Red Hat OpenStack Platform (RHOSP) services to provide networking for pods and Services.

Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.

Kuryr components are installed as pods in OpenShift Container Platform using the **openshift-kuryr** namespace:

- **kuryr-controller** - a single service instance installed on a **master** node. This is modeled in OpenShift Container Platform as a **Deployment** object.
- **kuryr-cni** - a container installing and configuring Kuryr as a CNI driver on each OpenShift Container Platform node. This is modeled in OpenShift Container Platform as a **DaemonSet** object.

The Kuryr controller watches the OpenShift Container Platform API server for pod, service, and namespace create, update, and delete events. It maps the OpenShift Container Platform API calls to corresponding objects in Neutron and Octavia. This means that every network solution that implements

the Neutron trunk port functionality can be used to back OpenShift Container Platform via Kuryr. This includes open source solutions such as Open vSwitch (OVS) and Open Virtual Network (OVN) as well as Neutron-compatible commercial SDNs.

Kuryr is recommended for OpenShift Container Platform deployments on encapsulated RHOSP tenant networks to avoid double encapsulation, such as running an encapsulated OpenShift Container Platform SDN over an RHOSP network.

If you use provider networks or tenant VLANs, you do not need to use Kuryr to avoid double encapsulation. The performance benefit is negligible. Depending on your configuration, though, using Kuryr to avoid having two overlays might still be beneficial.

Kuryr is not recommended in deployments where all of the following criteria are true:

- The RHOSP version is less than 16.
- The deployment uses UDP services, or a large number of TCP services on few hypervisors.

or

- The **ovn-octavia** Octavia driver is disabled.
- The deployment uses a large number of TCP services on few hypervisors.

15.6.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr

When using Kuryr SDN, the pods, services, namespaces, and network policies are using resources from the RHOSP quota; this increases the minimum requirements. Kuryr also has some additional requirements on top of what a default install requires.

Use the following quota to satisfy a default cluster's minimum requirements:

Table 15.23. Recommended resources for a default OpenShift Container Platform cluster on RHOSP with Kuryr

Resource	Value
Floating IP addresses	3 - plus the expected number of Services of LoadBalancer type
Ports	1500 - 1 needed per Pod
Routers	1
Subnets	250 - 1 needed per Namespace/Project
Networks	250 - 1 needed per Namespace/Project
RAM	112 GB
vCPUs	28

Resource	Value
Volume storage	275 GB
Instances	7
Security groups	250 - 1 needed per Service and per NetworkPolicy
Security group rules	1000
Load balancers	100 - 1 needed per Service
Load balancer listeners	500 - 1 needed per Service-exposed port
Load balancer pools	500 - 1 needed per Service-exposed port

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the **switoperator** role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

IMPORTANT

If you are using Red Hat OpenStack Platform (RHOSP) version 16 with the Amphora driver rather than the OVN Octavia driver, security groups are associated with service accounts instead of user projects.

Take the following notes into consideration when setting resources:

- The number of ports that are required is larger than the number of pods. Kuryr uses ports pools to have pre-created ports ready to be used by pods and speed up the pods' booting time.
- Each network policy is mapped into an RHOSP security group, and depending on the **NetworkPolicy** spec, one or more rules are added to the security group.
- Each service is mapped to an RHOSP load balancer. Consider this requirement when estimating the number of security groups required for the quota.
If you are using RHOSP version 15 or earlier, or the **ovn-octavia driver**, each load balancer has a security group with the user project.
- The quota does not account for load balancer resources (such as VM resources), but you must consider these resources when you decide the RHOSP deployment's size. The default installation will have more than 50 load balancers; the clusters must be able to accommodate them.

If you are using RHOSP version 16 with the OVN Octavia driver enabled, only one load balancer VM is generated; services are load balanced through OVN flows.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

To enable Kuryr SDN, your environment must meet the following requirements:

- Run RHOSP 13+.
- Have Overcloud with Octavia.
- Use Neutron Trunk ports extension.
- Use **openvswitch** firewall driver if ML2/OVS Neutron driver is used instead of **ovs-hybrid**.

15.6.3.1. Increasing quota

When using Kuryr SDN, you must increase quotas to satisfy the Red Hat OpenStack Platform (RHOSP) resources used by pods, services, namespaces, and network policies.

Procedure

- Increase the quotas for a project by running the following command:

```
$ sudo openstack quota set --secgroups 250 --secgroup-rules 1000 --ports 1500 --subnets 250 --networks 250 <project>
```

15.6.3.2. Configuring Neutron

Kuryr CNI leverages the Neutron Trunks extension to plug containers into the Red Hat OpenStack Platform (RHOSP) SDN, so you must use the **trunks** extension for Kuryr to properly work.

In addition, if you leverage the default ML2/OVS Neutron driver, the firewall must be set to **openvswitch** instead of **ovs_hybrid** so that security groups are enforced on trunk supports and Kuryr can properly handle network policies.

15.6.3.3. Configuring Octavia

Kuryr SDN uses Red Hat OpenStack Platform (RHOSP)'s Octavia LBaaS to implement OpenShift Container Platform services. Thus, you must install and configure Octavia components in RHOSP to use Kuryr SDN.

To enable Octavia, you must include the Octavia service during the installation of the RHOSP Overcloud, or upgrade the Octavia service if the Overcloud already exists. The following steps for enabling Octavia apply to both a clean install of the Overcloud or an Overcloud update.

NOTE

The following steps only capture the key pieces required during the [deployment of RHOSP](#) when dealing with Octavia. It is also important to note that [registry methods](#) vary.

This example uses the local registry method.

Procedure

1. If you are using the local registry, create a template to upload the images to the registry. For example:

```
(undercloud) $ openstack overcloud container image prepare \
-e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
--namespace=registry.access.redhat.com/rhosp13 \
--push-destination=<local-ip-from-undercloud.conf>:8787 \
--prefix=openstack- \
--tag-from-label {version}-{product-version} \
--output-env-file=/home/stack/templates/overcloud_images.yaml \
--output-images-file /home/stack/local_registry_images.yaml
```

2. Verify that the **local_registry_images.yaml** file contains the Octavia images. For example:

```
...
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-api:13.0-43
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-health-manager:13.0-45
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-housekeeping:13.0-45
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-worker:13.0-44
  push_destination: <local-ip-from-undercloud.conf>:8787
```

NOTE

The Octavia container versions vary depending upon the specific RHOSP release installed.

3. Pull the container images from **registry.redhat.io** to the Undercloud node:

```
(undercloud) $ sudo openstack overcloud container image upload \
--config-file /home/stack/local_registry_images.yaml \
--verbose
```

This may take some time depending on the speed of your network and Undercloud disk.

4. Since an Octavia load balancer is used to access the OpenShift Container Platform API, you must increase their listeners' default timeouts for the connections. The default timeout is 50 seconds. Increase the timeout to 20 minutes by passing the following file to the Overcloud deploy command:

```
(undercloud) $ cat octavia_timeouts.yaml
parameter_defaults:
  OctaviaTimeoutClientData: 1200000
  OctaviaTimeoutMemberData: 1200000
```

NOTE

This is not needed for RHOSP 13.0.13+.

5. Install or update your Overcloud environment with Octavia:

```
$ openstack overcloud deploy --templates \
-e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
-e octavia_timeouts.yaml
```

NOTE

This command only includes the files associated with Octavia; it varies based on your specific installation of RHOSP. See the RHOSP documentation for further information. For more information on customizing your Octavia installation, see [installation of Octavia using Director](#).

NOTE

When leveraging Kuryr SDN, the Overcloud installation requires the Neutron **trunk** extension. This is available by default on director deployments. Use the **openvswitch** firewall instead of the default **ovs-hybrid** when the Neutron backend is ML2/OVS. There is no need for modifications if the backend is ML2/OVN.

6. In RHOSP versions earlier than 13.0.13, add the project ID to the **octavia.conf** configuration file after you create the project.

- To enforce network policies across services, like when traffic goes through the Octavia load balancer, you must ensure Octavia creates the Amphora VM security groups on the user project.

This change ensures that required load balancer security groups belong to that project, and that they can be updated to enforce services isolation.

NOTE

This task is unnecessary in RHOSP version 13.0.13 or later.

Octavia implements a new ACL API that restricts access to the load balancers VIP.

- a. Get the project ID

```
$ openstack project show <project>
```

Example output

Field	Value
description	
domain_id	default
enabled	True
id	PROJECT_ID
is_domain	False
name	*<project>*
parent_id	default
tags	[]

- b. Add the project ID to **octavia.conf** for the controllers.

- i. Source the **stackrc** file:

```
$ source stackrc # Undercloud credentials
```

- ii. List the Overcloud controllers:

```
$ openstack server list
```

Example output

ID	Image	Flavor	Name	Status	Networks
6bef8e73-2ba5-4860-a0b1-3937f8ca7e01			controller-0	ACTIVE	ctlplane=192.168.24.8 overcloud-full controller
dd43173a-ab26-47f8-a2dc-8473b4a67ab9			compute-0	ACTIVE	ctlplane=192.168.24.6 overcloud-full compute

- iii. SSH into the controller(s).

```
$ ssh heat-admin@192.168.24.8
```

- iv. Edit the **octavia.conf** file to add the project into the list of projects where Amphora security groups are on the user's account.

```
# List of project IDs that are allowed to have Load balancer security groups  
# belonging to them.  
amp_secgroup_allowed_projects = PROJECT_ID
```

- c. Restart the Octavia worker so the new configuration loads.

```
controller-0$ sudo docker restart octavia_worker
```

NOTE

Depending on your RHOSP environment, Octavia might not support UDP listeners. If you use Kuryr SDN on RHOSP version 13.0.13 or earlier, UDP services are not supported. RHOSP version 16 or later support UDP.

15.6.3.3.1. The Octavia OVN Driver

Octavia supports multiple provider drivers through the Octavia API.

To see all available Octavia provider drivers, on a command line, enter:

```
$ openstack loadbalancer provider list
```

Example output

name	description
amphora	The Octavia Amphora driver.
octavia	Deprecated alias of the Octavia Amphora driver.
ovn	Octavia OVN driver.

Beginning with RHOSP version 16, the Octavia OVN provider driver (**ovn**) is supported on OpenShift Container Platform on RHOSP deployments.

ovn is an integration driver for the load balancing that Octavia and OVN provide. It supports basic load balancing capabilities, and is based on OpenFlow rules. The driver is automatically enabled in Octavia by Director on deployments that use OVN Neutron ML2.

The Amphora provider driver is the default driver. If **ovn** is enabled, however, Kuryr uses it.

If Kuryr uses **ovn** instead of Amphora, it offers the following benefits:

- Decreased resource requirements. Kuryr does not require a load balancer VM for each service.
- Reduced network latency.
- Increased service creation speed by using OpenFlow rules instead of a VM for each service.
- Distributed load balancing actions across all nodes instead of centralized on Amphora VMs.

15.6.3.4. Known limitations of installing with Kuryr

Using OpenShift Container Platform with Kuryr SDN has several known limitations.

RHOSP general limitations

Using OpenShift Container Platform with Kuryr SDN has several limitations that apply to all versions and environments:

- Service** objects with the **NodePort** type are not supported.
- Clusters that use the OVN Octavia provider driver support **Service** objects for which the **.spec.selector** property is unspecified only if the **.subsets.addresses** property of the **Endpoints** object includes the subnet of the nodes or pods.
- If the subnet on which machines are created is not connected to a router, or if the subnet is connected, but the router has no external gateway set, Kuryr cannot create floating IPs for **Service** objects with type **LoadBalancer**.

RHOSP version limitations

Using OpenShift Container Platform with Kuryr SDN has several limitations that depend on the RHOSP version.

- RHOSP versions before 16 use the default Octavia load balancer driver (Amphora). This driver requires that one Amphora load balancer VM is deployed per OpenShift Container Platform service. Creating too many services can cause you to run out of resources.
Deployments of later versions of RHOSP that have the OVN Octavia driver disabled also use the Amphora driver. They are subject to the same resource concerns as earlier versions of RHOSP.
- Octavia RHOSP versions before 13.0.13 do not support UDP listeners. Therefore, OpenShift Container Platform UDP services are not supported.
- Octavia RHOSP versions before 13.0.13 cannot listen to multiple protocols on the same port. Services that expose the same port to different protocols, like TCP and UDP, are not supported.

RHOSP environment limitations

There are limitations when using Kuryr SDN that depend on your deployment environment.

Because of Octavia's lack of support for the UDP protocol and multiple listeners, if the RHOSP version is earlier than 13.0.13, Kuryr forces pods to use TCP for DNS resolution.

In Go versions 1.12 and earlier, applications that are compiled with CGO support disabled use UDP only. In this case, the native Go resolver does not recognize the **use-vc** option in **resolv.conf**, which controls whether TCP is forced for DNS resolution. As a result, UDP is still used for DNS resolution, which fails.

To ensure that TCP forcing is allowed, compile applications either with the environment variable **CGO_ENABLED** set to **1**, i.e. **CGO_ENABLED=1**, or ensure that the variable is absent.

In Go versions 1.13 and later, TCP is used automatically if DNS resolution using UDP fails.

NOTE

musl-based containers, including Alpine-based containers, do not support the **use-vc** option.

RHOSP upgrade limitations

As a result of the RHOSP upgrade process, the Octavia API might be changed, and upgrades to the Amphora images that are used for load balancers might be required.

You can address API changes on an individual basis.

If the Amphora image is upgraded, the RHOSP operator can handle existing load balancer VMs in two ways:

- Upgrade each VM by triggering a [load balancer failover](#).
- Leave responsibility for upgrading the VMs to users.

If the operator takes the first option, there might be short downtimes during failovers.

If the operator takes the second option, the existing load balancers will not support upgraded Octavia API features, like UDP listeners. In this case, users must recreate their Services to use these features.

IMPORTANT

If OpenShift Container Platform detects a new Octavia version that supports UDP load balancing, it recreates the DNS service automatically. The service recreation ensures that the service default supports UDP load balancing.

The recreation causes the DNS service approximately one minute of downtime.

15.6.3.5. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

15.6.3.6. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

15.6.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

15.6.5. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules' repositories and then download them.

NOTE

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

Prerequisites

- Python 3 is installed on your machine.

Procedure

1. On a command line, add the repositories:

- a. Register with Red Hat Subscription Manager:

```
$ sudo subscription-manager register # If not done already
```

- b. Pull the latest subscription data:

```
$ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
```

- c. Disable the current repositories:

```
$ sudo subscription-manager repos --disable=* # If not done already
```

- d. Add the required repositories:

```
$ sudo subscription-manager repos \
--enable=rhel-8-for-x86_64-baseos-rpms \
--enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
--enable=ansible-2.9-for-rhel-8-x86_64-rpms \
--enable=rhel-8-for-x86_64-appstream-rpms
```

2. Install the modules:

```
$ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr
```

3. Ensure that the **python** command points to **python3**:

```
$ sudo alternatives --set python /usr/bin/python3
```

15.6.6. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

Prerequisites

- The curl command-line tool is available on your machine.

Procedure

- To download the playbooks to your working directory, run the following script from a command line:

```
$ xargs -n 1 curl -O <<< '  
    https://raw.githubusercontent.com/openshift/installer/release-  
4.9/upi/openstack/bootstrap.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-  
4.9/upi/openstack/common.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-  
4.9/upi/openstack/compute-nodes.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/control-  
plane.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-  
4.9/upi/openstack/inventory.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-  
4.9/upi/openstack/network.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/security-  
groups.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-  
bootstrap.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-  
compute-nodes.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-  
control-plane.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-  
load-balancers.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-  
network.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-  
security-groups.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-  
containers.yaml'
```

The playbooks are downloaded to your machine.

IMPORTANT

During the installation process, you can modify the playbooks to configure your deployment.

Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.

IMPORTANT

You must match any edits you make in the **bootstrap.yaml**, **compute-nodes.yaml**, **control-plane.yaml**, **network.yaml**, and **security-groups.yaml** files to the corresponding playbooks that are prefixed with **down-**. For example, edits to the **bootstrap.yaml** file must be reflected in the **down-bootstrap.yaml** file, too. If you do not edit both files, the supported cluster removal process will fail.

15.6.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the [Infrastructure Provider](#) page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

- From the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

15.6.8. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

- If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> ①
```

- Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

- View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name>
```

1

- 1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

15.6.9. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

Prerequisites

- The RHOSP CLI is installed.

Procedure

1. Log in to the Red Hat Customer Portal's [Product Downloads page](#).
2. Under **Version**, select the most recent release of OpenShift Container Platform 4.9 for Red Hat Enterprise Linux (RHEL) 8.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the *Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW)* .
4. Decompress the image.

NOTE

You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like **.gz** or **.tgz**. To find out if or how the file is compressed, in a command line, enter:

```
$ file <name_of_downloaded_file>
```

5. From the image that you downloaded, create an image that is named **rhcoss** in your cluster by using the RHOSP CLI:

```
$ openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-  
$(RHCOS_VERSION)-openstack.qcow2 rhcos
```

IMPORTANT

Depending on your RHOSP environment, you might be able to upload the image in either [.raw](#) or [.qcow2](#) formats. If you use Ceph, you must use the [.raw](#) format.

WARNING

If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

After you upload the image to RHOSP, it is usable in the installation process.

15.6.10. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Configure OpenStack's networking service to have DHCP agents forward instances' DNS queries

Procedure

- Using the RHOSP CLI, verify the name and ID of the 'External' network:

```
$ openstack network list --long -c ID -c Name -c "Router Type"
```

Example output

ID	Name	Router Type
148a8023-62a7-4672-b018-003462f8d7dc	public_network	External

A network with an external router type appears in the network list. If at least one does not, see [Creating a default floating IP network](#) and [Creating a default provider network](#).

NOTE

If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see [Neutron trunk port](#).

15.6.11. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

15.6.11.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

Procedure

- Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

```
$ openstack floating ip create --description "API <cluster_name>.<base_domain>"<external_network>
```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

```
$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>"<external_network>
```

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:

```
$ openstack floating ip create --description "bootstrap machine" <external_network>
```

4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

NOTE

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

5. Add the FIPs to the **inventory.yaml** file as the values of the following variables:

- **os_api_fip**
- **os_bootstrap_fip**
- **os_ingress_fip**

If you use these values, you must also enter an external network as the value of the **os_external_network** variable in the **inventory.yaml** file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

15.6.11.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the **inventory.yaml** file, do not define the following variables:

- **os_api_fip**
- **os_bootstrap_fip**
- **os_ingress_fip**

If you cannot provide an external network, you can also leave **os_external_network** blank. If you do not provide a value for **os_external_network**, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the **wait-for** command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

15.6.12. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called **clouds.yaml**. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the **clouds.yaml** file:

- If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.

IMPORTANT

Remember to add a password to the **auth** field. You can also keep secrets in a [separate file](#) from **clouds.yaml**.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about **clouds.yaml**, see [Config files](#) in the RHOSP documentation.

```
clouds:
shiftstack:
auth:
auth_url: http://10.10.14.42:5000/v3
project_name: shiftstack
username: shiftstack_user
password: XXX
user_domain_name: Default
project_domain_name: Default
dev-env:
region_name: RegionOne
auth:
username: 'devuser'
password: XXX
project_name: 'devonly'
auth_url: 'https://10.10.14.22:5001/v2.0'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
 - a. Copy the certificate authority file to your machine.
 - b. Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

```
clouds:
  shiftstack:
    ...
    cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the **clouds.yaml** file in one of the following locations:
 - a. The value of the **OS_CLIENT_CONFIG_FILE** environment variable
 - b. The current directory
 - c. A Unix-specific user configuration directory, for example **~/.config/openstack/clouds.yaml**
 - d. A Unix-specific site configuration directory, for example **/etc/openstack/clouds.yaml**

The installation program searches for **clouds.yaml** in that order.

15.6.13. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- Have the **imageContentSources** values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.
- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.
- Obtain service principal permissions at the subscription level.

Procedure

1. Create the **install-config.yaml** file.

- a. Change to the directory that contains the installation program and run the following command:

```
 $ ./openshift-install create install-config --dir=<installation_directory> ①
```

- ① For **<installation_directory>**, specify the directory name to store the files that the installation program creates.

IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

- b. At the prompts, provide the configuration details for your cloud:

- i. Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **openstack** as the platform to target.
 - iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.
 - iv. Specify the floating IP address to use for external access to the OpenShift API.
 - v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.
 - vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.
 - vii. Enter a name for your cluster. The name must be 14 or fewer characters long.
 - viii. Paste the pull secret that you obtained from the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site.
2. In the **install-config.yaml** file, set the value of **platform.openstack.clusterOSImage** to the image location or name. For example:

```
platform:  
  openstack:  
    clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-  
    openstack.x86_64.qcow2.gz?  
    sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265
```

3. Edit the **install-config.yaml** file to provide the additional information that is required for an installation in a restricted network.
 - a. Update the **pullSecret** value to contain the authentication information for your registry;

```
pullSecret: '{"auths": {"<mirror_host_name>:5000": {"auth": "<credentials>", "email": "you@example.com"}}}'
```

For **<mirror_host_name>**, specify the registry domain name that you specified in the certificate for your mirror registry, and for **<credentials>**, specify the base64-encoded user name and password for your mirror registry.

- b. Add the **additionalTrustBundle** parameter and value.

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

- c. Add the image content resources, which look like this excerpt:

```
imageContentSources:  
- mirrors:  
  - <mirror_host_name>:5000/<repo_name>/release  
    source: quay.example.com/openshift-release-dev/ocp-release  
- mirrors:  
  - <mirror_host_name>:5000/<repo_name>/release  
    source: registry.example.com/ocp/release
```

To complete these values, use the **imageContentSources** that you recorded during mirror registry creation.

4. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.
 5. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file **install-config.yaml** in the directory that you specified.

15.6.14. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster's

platform. When you create the **install-config.yaml** installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the **install-config.yaml** file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

IMPORTANT

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

15.6.14.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 15.24. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>. <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}} .	String of lowercase letters, hyphens (-), and periods (.), such as dev . The string must be 14 characters or fewer long.

Parameter	Description	Values
platform	The configuration for the specific platform upon which to perform the installation: aws , baremetal , azure , openstack , ovirt , vsphere , or <code>{}</code> . For additional information about platform . <platform> parameters, consult the table for your specific platform that follows.	Object
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths":{ "cloud.openshift.com":{ "auth":"b3Blb=", "email":"you@example.com" }, "quay.io":{ "auth":"b3Blb=", "email":"you@example.com" } } }</pre>

15.6.14.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 15.25. Network parameters

Parameter	Description	Values
networking	The configuration for the cluster network.	<p>Object</p>  <p>NOTE</p> <p>You cannot modify parameters specified by the networking object after installation.</p>

Parameter	Description	Values
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23 . If you specify multiple IP address blocks, the blocks must not overlap.	An array of objects. For example: <pre>networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</pre>
networking.clusterNetwork.cidr	Required if you use networking.clusterNetwork . An IP address block. An IPv4 network.	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{(32 - 23)} - 2$) pod IP addresses.	A subnet prefix. The default value is 23 .
networking.serviceNetwork	The IP address block for services. The default value is 172.30.0.0/16 . The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.	An array with an IP address block in CIDR format. For example: <pre>networking: serviceNetwork: - 172.30.0.0/16</pre>
networking.machineNetwork	The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.	An array of objects. For example: <pre>networking: machineNetwork: - cidr: 10.0.0.0/16</pre>

Parameter	Description	Values
networking.machineNetwork.cidr	Required if you use networking.machineNetwork . An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24 .	<p>An IP network block in CIDR notation. For example, 10.0.0.0/16.</p>  <p>NOTE Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.</p>

15.6.14.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

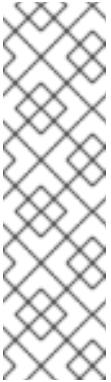

Table 15.26. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String

Parameter	Description	Values
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String

Parameter	Description	Values
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.	Mint, Passthrough, Manual , or an empty string ("").
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>NOTE</p> <p>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the <i>Cloud Credential Operator</i> entry in the <i>Red Hat Operators</i> reference content.</p>	false or true
imageContentSources	 <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.

Parameter	Description	Values
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.	Internal or External . The default value is External . Setting this field to Internal is not supported on non-cloud platforms.
sshKey	The SSH key or keys to authenticate access your cluster machines.  NOTE For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.	One or more keys. For example: sshKey: <key1> <key2> <key3>

15.6.14.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

Table 15.27. Additional RHOSP parameters

Parameter	Description	Values
compute.platform.openstack.rootVolume.size	For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.	Integer, for example 30 .
compute.platform.openstack.rootVolume.type	For compute machines, the root volume's type.	String, for example performance .

Parameter	Description	Values
controlPlane.platform.openstack.rootVolume.size	For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.	Integer, for example 30 .
controlPlane.platform.openstack.rootVolume.type	For control plane machines, the root volume's type.	String, for example performance .
platform.openstack.cloud	The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file.	String, for example MyCloud .
platform.openstack.externalNetwork	The RHOSP external network name to be used for installation.	String, for example external .
platform.openstack.computeFlavor	The RHOSP flavor to use for control plane and compute machines. This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.	String, for example m1.xlarge .

15.6.14.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

Table 15.28. Optional RHOSP parameters

Parameter	Description	Values
-----------	-------------	--------

Parameter	Description	Values
compute.platform.openstack.additionalNetworkIDs	Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.	A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .
compute.platform.openstack.additionalSecurityGroupIDs	Additional security groups that are associated with compute machines.	A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7 .
compute.platform.openstack.zones	RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.	A list of strings. For example, ["zone-1", "zone-2"] .
compute.platform.openstack.rootVolume.zones	For compute machines, the availability zone to install root volumes on. If you do not set a value for this parameter, the installer selects the default availability zone.	A list of strings, for example ["zone-1", "zone-2"] .
controlPlane.platform.openstack.additionalNetworkIDs	Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.	A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .
controlPlane.platform.openstack.additionalSecurityGroupIDs	Additional security groups that are associated with control plane machines.	A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7 .

Parameter	Description	Values
controlPlane.platform.openstack.zones	<p>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured.</p> <p>On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</p>	A list of strings. For example, ["zone-1", "zone-2"] .
controlPlane.platform.openstack.rootVolume.zones	<p>For control plane machines, the availability zone to install root volumes on. If you do not set this value, the installer selects the default availability zone.</p>	A list of strings, for example ["zone-1", "zone-2"] .
platform.openstack.clusterOSImage	<p>The location from which the installer downloads the RHCOS image.</p> <p>You must set this parameter to perform an installation in a restricted network.</p>	<p>An HTTP or HTTPS URL, optionally with an SHA-256 checksum.</p> <p>For example, http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d. The value can also be the name of an existing Glance image, for example my-rhcos.</p>

Parameter	Description	Values
platform.openstack.clusterOSImageProperties	<p>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image.</p> <p>You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi.</p> <p>You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</p>	A list of key-value string pairs. For example, <code>["hw_scsi_model": "virtio-scsi", "hw_disk_bus": "scsi"]</code> .
platform.openstack.defaultMachinePlatform	The default machine pool platform configuration.	<pre>{ "type": "ml.large", "rootVolume": { "size": 30, "type": "performance" } }</pre>
platform.openstack.ingressFloatingIP	An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.	An IP address, for example 128.0.0.1 .
platform.openstack.apiFloatingIP	An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property.	An IP address, for example 128.0.0.1 .
platform.openstack.externalDNS	IP addresses for external DNS servers that cluster instances use for DNS resolution.	A list of IP addresses as strings. For example, <code>["8.8.8", "192.168.1.12"]</code> .

Parameter	Description	Values
platform.openstack.machinesSubnet	<p>The UUID of a RHOSP subnet that the cluster's nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.</p> <p>The first item in networking.machineNetwork must match the value of machinesSubnet.</p> <p>If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.</p>	A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .

15.6.14.6. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet's GUID is passed as the value of **platform.openstack.machinesSubnet** in the **install-config.yaml** file.

This subnet is used as the cluster's primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the **platform.openstack.machinesSubnet** property to the subnet's UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by **platform.openstack.machinesSubnet** has DHCP enabled.
- The CIDR of **platform.openstack.machinesSubnet** matches the CIDR of **networking.machineNetwork**.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the **platform.openstack.machinesSubnet** subnet must be attached to a router that is connected to the **externalNetwork** network.
- If the **platform.openstack.machinesSubnet** value is set in the **install-config.yaml** file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the **platform.openstack.externalIDNS** property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network's CIDR block. To override these default values, set values for **platform.openstack.apiVIP** and **platform.openstack.ingressVIP** that are outside of the DHCP allocation pool.

15.6.14.7. Sample customized `install-config.yaml` file for RHOSP with Kuryr

To deploy with Kuryr SDN instead of the default OpenShift SDN, you must modify the **install-config.yaml** file to include **Kuryr** as the desired **networking.networkType** and proceed with the default OpenShift Container Platform SDN installation steps. This sample **install-config.yaml** demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program.

```
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
- name: worker
  platform:
    openstack:
      type: ml.large
    replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
  - cidr: 10.0.0.0/16
  serviceNetwork:
  - 172.30.0.0/16 ①
networkType: Kuryr
platform:
  openstack:
    cloud: mycloud
    externalNetwork: external
    computeFlavor: m1.xlarge
    apiFloatingIP: 128.0.0.1
    trunkSupport: true ②
    octaviaSupport: true ③
pullSecret: '{"auths": ...}'
sshKey: ssh-ed25519 AAAA...
```

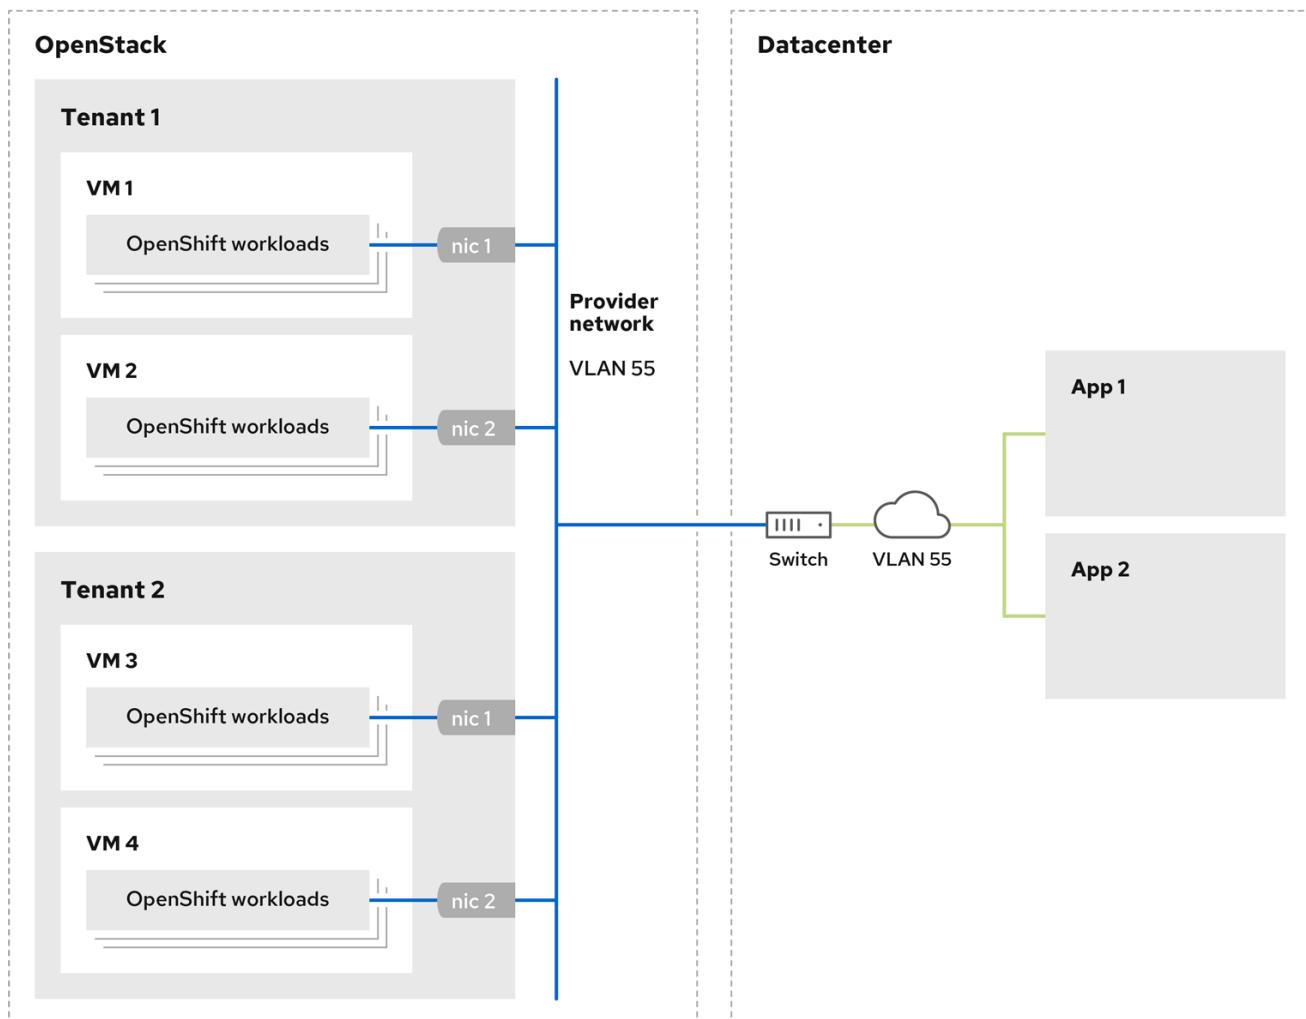

- 1 The Amphora Octavia driver creates two ports per load balancer. As a result, the service subnet that the installer creates is twice the size of the CIDR that is specified as the value of the **serviceNetwork** property. The larger range is required to prevent IP address conflicts.
- 2 Both **trunkSupport** and **octaviaSupport** are automatically discovered by the installer, so there is no need to set them. But if your environment does not meet both requirements, Kuryr SDN will not properly work. Trunks are needed to connect the pods to the RHOSP network and Octavia is required to create the OpenShift Container Platform services.

15.6.14.8. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:

OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

NOTE

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in [the RHOSP documentation](#).

15.6.14.8.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The [RHOSP networking service \(Neutron\) is enabled](#) and accessible through the RHOSP networking API.
- The RHOSP networking service has the [port security and allowed address pairs extensions enabled](#).
- The provider network can be shared with other tenants.

TIP

Use the **openstack network create** command with the **--share** flag to create a network that can be shared.

- The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

TIP

To create a network for a project that is named "openshift," enter the following command

```
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command

```
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read [the provider networks documentation](#).

If the cluster is owned by the **admin** user, you must run the installer as that user to create ports on the network.

IMPORTANT

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is **169.254.169.254** by default.

Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```
$ openstack subnet create --dhcp --host-route
destination=169.254.169.254/32,gateway=192.0.2.2 ...
```

- Optional: To secure the network, create [role-based access control \(RBAC\)](#) rules that limit network access to a single project.

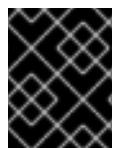

15.6.14.8.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network. .Prerequisites

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".

Procedure

- In a text editor, open the **install-config.yaml** file.
- Set the value of the **platform.openstack.apiVIP** property to the IP address for the API VIP.
- Set the value of the **platform.openstack.ingressVIP** property to the IP address for the Ingress VIP.
- Set the value of the **platform.openstack.machinesSubnet** property to the UUID of the provider network subnet.
- Set the value of the **networking.machineNetwork.cidr** property to the CIDR block of the provider network subnet.

IMPORTANT

The **platform.openstack.apiVIP** and **platform.openstack.ingressVIP** properties must both be unassigned IP addresses from the **networking.machineNetwork.cidr** block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```
...
platform:
  openstack:
    apiVIP: 192.0.2.13
    ingressVIP: 192.0.2.23
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
```

```
# ...
networking:
  machineNetwork:
    - cidr: 192.0.2.0/24
```

**WARNING**

You cannot set the **platform.openstack.externalNetwork** or **platform.openstack.externalDNS** parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the **install-config.yaml** file to deploy the cluster on the provider network.

TIP

You can add additional networks, including provider networks, to the **platform.openstack.additionalNetworkIDs** list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).

15.6.14.9. Kuryr ports pools

A Kuryr ports pool maintains a number of ports on standby for pod creation.

Keeping ports on standby minimizes pod creation time. Without ports pools, Kuryr must explicitly request port creation or deletion whenever a pod is created or deleted.

The Neutron ports that Kuryr uses are created in subnets that are tied to namespaces. These pod ports are also added as subports to the primary port of OpenShift Container Platform cluster nodes.

Because Kuryr keeps each namespace in a separate subnet, a separate ports pool is maintained for each namespace-worker pair.

Prior to installing a cluster, you can set the following parameters in the **cluster-network-03-config.yml** manifest file to configure ports pool behavior:

- The **enablePortPoolsPrepopulation** parameter controls pool prepopulation, which forces Kuryr to add ports to the pool when it is created, such as when a new host is added, or a new namespace is created. The default value is **false**.
- The **poolMinPorts** parameter is the minimum number of free ports that are kept in the pool. The default value is **1**.
- The **poolMaxPorts** parameter is the maximum number of free ports that are kept in the pool. A value of **0** disables that upper bound. This is the default setting.
If your OpenStack port quota is low, or you have a limited number of IP addresses on the pod network, consider setting this option to ensure that unneeded ports are deleted.

- The **poolBatchPorts** parameter defines the maximum number of Neutron ports that can be created at once. The default value is **3**.

15.6.14.10. Adjusting Kuryr ports pools during installation

During installation, you can configure how Kuryr manages Red Hat OpenStack Platform (RHOSP) Neutron ports to control the speed and efficiency of pod creation.

Prerequisites

- Create and modify the **install-config.yaml** file.

Procedure

1. From a command line, create the manifest files:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

- 1 For **<installation_directory>**, specify the name of the directory that contains the **install-config.yaml** file for your cluster.

2. Create a file that is named **cluster-network-03-config.yml** in the **<installation_directory>/manifests** directory:

```
$ touch <installation_directory>/manifests/cluster-network-03-config.yml ①
```

- 1 For **<installation_directory>**, specify the directory name that contains the **manifests**/ directory for your cluster.

After creating the file, several network configuration files are in the **manifests**/ directory, as shown:

```
$ ls <installation_directory>/manifests/cluster-network-*
```

Example output

```
cluster-network-01-crd.yaml  
cluster-network-02-config.yaml  
cluster-network-03-config.yaml
```

3. Open the **cluster-network-03-config.yml** file in an editor, and enter a custom resource (CR) that describes the Cluster Network Operator configuration that you want:

```
$ oc edit networks.operator.openshift.io cluster
```

4. Edit the settings to meet your requirements. The following file is provided as an example:

```
apiVersion: operator.openshift.io/v1  
kind: Network  
metadata:  
  name: cluster
```

```

spec:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  serviceNetwork:
    - 172.30.0.0/16
  defaultNetwork:
    type: Kuryr
    kuryrConfig:
      enablePortPoolsPrepopulation: false ①
      poolMinPorts: 1 ②
      poolBatchPorts: 3 ③
      poolMaxPorts: 5 ④
    openstackServiceNetwork: 172.30.0.0/15 ⑤

```

- ① Set the value of **enablePortPoolsPrepopulation** to **true** to make Kuryr create new Neutron ports after a namespace is created or a new node is added to the cluster. This setting raises the Neutron ports quota but can reduce the time that is required to spawn pods. The default value is **false**.
- ② Kuryr creates new ports for a pool if the number of free ports in that pool is lower than the value of **poolMinPorts**. The default value is **1**.
- ③ **poolBatchPorts** controls the number of new ports that are created if the number of free ports is lower than the value of **poolMinPorts**. The default value is **3**.
- ④ If the number of free ports in a pool is higher than the value of **poolMaxPorts**, Kuryr deletes them until the number matches that value. Setting this value to **0** disables this upper bound, preventing pools from shrinking. The default value is **0**.
- ⑤ The **openStackServiceNetwork** parameter defines the CIDR range of the network from which IP addresses are allocated to RHOSP Octavia's LoadBalancers.

If this parameter is used with the Amphora driver, Octavia takes two IP addresses from this network for each load balancer: one for OpenShift and the other for VRRP connections. Because these IP addresses are managed by OpenShift Container Platform and Neutron respectively, they must come from different pools. Therefore, the value of **openStackServiceNetwork** must be at least twice the size of the value of **serviceNetwork**, and the value of **serviceNetwork** must overlap entirely with the range that is defined by **openStackServiceNetwork**.

The CNO verifies that VRRP IP addresses that are taken from the range that is defined by this parameter do not overlap with the range that is defined by the **serviceNetwork** parameter.

If this parameter is not set, the CNO uses an expanded value of **serviceNetwork** that is determined by decrementing the prefix size by 1.

5. Save the **cluster-network-03-config.yml** file, and exit the text editor.
6. Optional: Back up the **manifests/cluster-network-03-config.yml** file. The installation program deletes the **manifests/** directory while creating the cluster.

15.6.14.11. Setting a custom subnet for machines

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.

Prerequisites

- You have the **install-config.yaml** file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains **install-config.yaml**.
2. From that directory, either run a script to edit the **install-config.yaml** file or update the file manually:

- To set the value by using a script, run:

```
$ python -c '
import yaml;
path = "install-config.yaml";
data = yaml.safe_load(open(path));
data["networking"]["machineNetwork"] = [{"cidr": "192.168.0.0/18"}]; ①
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

① Insert a value that matches your intended Neutron subnet, e.g. **192.0.2.0/24**.

- To set the value manually, open the file and set the value of **networking.machineCIDR** to something that matches your intended Neutron subnet.

15.6.14.12. Emptying compute machine pools

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

Prerequisites

- You have the **install-config.yaml** file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains **install-config.yaml**.
2. From that directory, either run a script to edit the **install-config.yaml** file or update the file manually:
 - To set the value by using a script, run:

```
$ python -c '
import yaml;
path = "install-config.yaml";
```

```
data = yaml.safe_load(open(path));
data["compute"][0]["replicas"] = 0;
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

- To set the value manually, open the file and set the value of **compute.<first entry>.replicas** to **0**.

15.6.14.13. Modifying the network type

By default, the installation program selects the **OpenShiftSDN** network type. To use Kuryr instead, change the value in the installation configuration file that the program generated.

Prerequisites

- You have the file **install-config.yaml** that was generated by the OpenShift Container Platform installation program

Procedure

1. In a command prompt, browse to the directory that contains **install-config.yaml**.
2. From that directory, either run a script to edit the **install-config.yaml** file or update the file manually:
 - To set the value by using a script, run:

```
$ python -c '
import yaml;
path = "install-config.yaml";
data = yaml.safe_load(open(path));
data["networking"]["networkType"] = "Kuryr";
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

- To set the value manually, open the file and set **networking.networkType** to "**Kuryr**".

15.6.15. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the **install-config.yaml** installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

Example output

```
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"  
INFO Consuming Install Config from target directory  
INFO Manifests created in: install_dir/manifests and install_dir/openshift
```

- 1 For **<installation_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

- 2 Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

```
$ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.
3. Check that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
 - a. Open the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file.
 - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
 - c. Save and exit the file.
 4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory> ①
```

- 1 For **<installation_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation_directory>/auth** directory:

5. Export the metadata file's **infraID** key as an environment variable:

```
$ export INFRA_ID=$(jq -r .infraID metadata.json)
```

TIP

Extract the **infraID** key from **metadata.json** and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

15.6.16. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

Prerequisites

- You have the bootstrap Ignition file that the installer program generates, **bootstrap.ign**.
- The infrastructure ID from the installer's metadata file is set as an environment variable (**\$INFRA_ID**).
 - If the variable is not set, see [Creating the Kubernetes manifest and Ignition config files](#)
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
 - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

Procedure

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the hostname and, if available, CA certificate file when it runs:

```
import base64
import json
import os
```

```

with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

    files = ignition['storage'].get('files', [])

    infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
    hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap\n').decode().strip()
    files.append(
    {
        'path': '/etc/hostname',
        'mode': 420,
        'contents': {
            'source': 'data:text/plain;charset=utf-8;base64,' + hostname_b64
        }
    })
}

ca_cert_path = os.environ.get('OS_CACERT', "")
if ca_cert_path:
    with open(ca_cert_path, 'r') as f:
        ca_cert = f.read().encode()
        ca_cert_b64 = base64.standard_b64encode(ca_cert).decode().strip()

    files.append(
    {
        'path': '/opt/openshift/tls/cloud-ca-cert.pem',
        'mode': 420,
        'contents': {
            'source': 'data:text/plain;charset=utf-8;base64,' + ca_cert_b64
        }
    })
}

ignition['storage']['files'] = files;

with open('bootstrap.ign', 'w') as f:
    json.dump(ignition, f)

```

- Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

```
$ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign
<image_name>
```

- Get the image's details:

```
$ openstack image show <image_name>
```

Make a note of the **file** value; it follows the pattern **v2/images/<image_ID>/file**.

NOTE

Verify that the image you created is active.

- Retrieve the image service's public address:

```
$ openstack catalog show image
```

5. Combine the public address with the image **file** value and save the result as the storage location. The location follows the pattern **<image_service_public_URL>/v2/images/<image_ID>/file**.

6. Generate an auth token and save the token ID:

```
$ openstack token issue -c id -f value
```

7. Insert the following content into a file called **\$INFRA_ID-bootstrap-ignition.json** and edit the placeholders to match your own values:

```
{
  "ignition": {
    "config": {
      "merge": [
        {
          "source": "<storage_url>", ①
          "httpHeaders": [
            {
              "name": "X-Auth-Token", ②
              "value": "<token_ID>" ③
            }
          ]
        }
      ],
      "security": {
        "tls": {
          "certificateAuthorities": [
            {
              "source": "data:text/plain;charset=utf-8;base64,<base64_encoded_certificate>" ④
            }
          ]
        },
        "version": "3.2.0"
      }
    }
}
```

- ① Replace the value of **ignition.config.merge.source** with the bootstrap Ignition file storage URL.
- ② Set **name** in **httpHeaders** to "**X-Auth-Token**".
- ③ Set **value** in **httpHeaders** to your token's ID.
- ④ If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

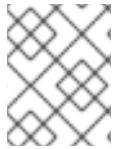

The bootstrap Ignition data will be passed to RHOSP during installation.

**WARNING**

The bootstrap Ignition file contains sensitive information, like **clouds.yaml** credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

15.6.17. Creating control plane Ignition config files on RHOSP

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.

**NOTE**

As with the bootstrap Ignition configuration, you must explicitly define a hostname for each control plane machine.

Prerequisites

- The infrastructure ID from the installation program's metadata file is set as an environment variable (**\$INFRA_ID**).
 - If the variable is not set, see "Creating the Kubernetes manifest and Ignition config files".

Procedure

- On a command line, run the following Python script:

```
$ for index in $(seq 0 2); do
    MASTER_HOSTNAME="$INFRA_ID-master-$index\n"
    python -c "import base64, json, sys;
ignition = json.load(sys.stdin);
storage = ignition.get('storage', {});
files = storage.get('files', []);
files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {'source':
'data:text/plain;charset=utf-8;base64,' +
base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(), 'verification': {}},
'filesystem': 'root'});
storage['files'] = files;
ignition['storage'] = storage
json.dump(ignition, sys.stdout)" <master.ign >"$INFRA_ID-master-$index-ignition.json"
done
```

You now have three control plane Ignition files: **<INFRA_ID>-master-0-ignition.json**, **<INFRA_ID>-master-1-ignition.json**, and **<INFRA_ID>-master-2-ignition.json**.

15.6.18. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.

Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

Procedure

1. Optional: Add an external network value to the **inventory.yaml** playbook:

Example external network value in the **inventory.yaml** Ansible playbook

```
...
# The public network providing connectivity to the cluster. If not
# provided, the cluster external connectivity must be provided in another
# way.

# Required for os_api_fip, os_ingress_fip, os_bootstrap_fip.
os_external_network: 'external'
...
```

IMPORTANT

If you did not provide a value for **os_external_network** in the **inventory.yaml** file, you must ensure that VMs can access Glance and an external connection yourself.

2. Optional: Add external network and floating IP (FIP) address values to the **inventory.yaml** playbook:

Example FIP values in the **inventory.yaml** Ansible playbook

```
...
# OpenShift API floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the Control Plane to
# serve the OpenShift API.
os_api_fip: '203.0.113.23'

# OpenShift Ingress floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the worker nodes to serve
# the applications.
os_ingress_fip: '203.0.113.19'

# If this value is non-empty, the corresponding floating IP will be
# attached to the bootstrap machine. This is needed for collecting logs
# in case of install failure.
os_bootstrap_fip: '203.0.113.20'
```

IMPORTANT

If you do not define values for **os_api_ip** and **os_ingress_ip**, you must perform post-installation network configuration.

If you do not define a value for **os_bootstrap_ip**, the installer cannot download debugging information from failed installations.

See "Enabling access to the environment" for more information.

3. On a command line, create security groups by running the **security-groups.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml security-groups.yaml
```

4. On a command line, create a network, subnet, and router by running the **network.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml network.yaml
```

5. Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:

```
$ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2> "$INFRA_ID-nodes"
```

15.6.19. Creating the bootstrap machine on RHOSP

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **bootstrap.yaml** Ansible playbooks are in a common directory.
- The **metadata.json** file that the installation program created is in the same directory as the Ansible playbooks.

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the **bootstrap.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml bootstrap.yaml
```

3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:

```
$ openstack console log show "$INFRA_ID-bootstrap"
```

15.6.20. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The infrastructure ID from the installation program's metadata file is set as an environment variable (**\$INFRA_ID**).
- The **inventory.yaml**, **common.yaml**, and **control-plane.yaml** Ansible playbooks are in a common directory.
- You have the three Ignition files that were created in "Creating control plane Ignition config files".

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. If the control plane Ignition config files aren't already in your working directory, copy them into it.
3. On a command line, run the **control-plane.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml control-plane.yaml
```

4. Run the following command to monitor the bootstrapping process:

```
$ openshift-install wait-for bootstrap-complete
```

You will see messages that confirm that the control plane machines are running and have joined the cluster:

```
INFO API v1.22.1 up
INFO Waiting up to 30m0s for bootstrapping to complete...
...
INFO It is now safe to remove the bootstrap resources
```

15.6.21. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.

- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

- ① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

15.6.22. Deleting bootstrap resources from RHOSP

Delete the bootstrap resources that you no longer need.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **down-bootstrap.yaml** Ansible playbooks are in a common directory.
- The control plane machines are running.
 - If you do not know the status of the machines, see "Verifying cluster status".

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the **down-bootstrap.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml down-bootstrap.yaml
```

The bootstrap port, server, and floating IP address are deleted.

**WARNING**

If you did not disable the bootstrap Ignition file URL earlier, do so now.

15.6.23. Creating compute machines on RHOSP

After standing up the control plane, create compute machines. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **compute-nodes.yaml** Ansible playbooks are in a common directory.
- The **metadata.json** file that the installation program created is in the same directory as the Ansible playbooks.
- The control plane is active.

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the playbook:

```
$ ansible-playbook -i inventory.yaml compute-nodes.yaml
```

Next steps

- Approve the certificate signing requests for the machines.

15.6.24. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.22.1
master-1	Ready	master	63m	v1.22.1
master-2	Ready	master	64m	v1.22.1

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

- Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-8b2br	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
csr-8vnps	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
...			

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

- If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approvers** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	Pending
csr-c57lv	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	Pending
...			

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	73m	v1.22.1
master-1	Ready	master	73m	v1.22.1
master-2	Ready	master	74m	v1.22.1
worker-0	Ready	worker	11m	v1.22.1
worker-1	Ready	worker	11m	v1.22.1

NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

15.6.25. Verifying a successful installation

Verify that the OpenShift Container Platform installation is complete.

Prerequisites

- You have the installation program (**openshift-install**)

Procedure

- On a command line, enter:

```
$ openshift-install --log-level debug wait-for install-complete
```

The program outputs the console URL, as well as the administrator's login information.

15.6.26. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

15.6.27. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- If you need to enable external access to node ports, [configure ingress cluster traffic by using a node port](#).
- If you did not configure RHOSP to accept application traffic over floating IP addresses, [configure RHOSP access with floating IP addresses](#).

15.7. INSTALLING A CLUSTER ON OPENSTACK ON YOUR OWN SR-IOV INFRASTRUCTURE

In OpenShift Container Platform 4.9, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure and uses single-root input/output virtualization (SR-IOV) networks to run compute machines.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, such as Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

15.7.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You verified that OpenShift Container Platform 4.9 is compatible with your RHOSP version by using the [Supported platforms for OpenShift clusters](#) section. You can also compare platform support across different versions by viewing the [OpenShift Container Platform on RHOSP support matrix](#).
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- You have an RHOSP account where you want to install OpenShift Container Platform.
- On the machine where you run the installation program, you have:
 - A single directory in which you can keep the files you create during the installation process
 - Python 3

15.7.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

15.7.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

Table 15.29. Recommended resources for a default OpenShift Container Platform cluster on RHOSP

Resource	Value
Floating IP addresses	3
Ports	15
Routers	1
Subnets	1
RAM	112 GB
vCPUs	28
Volume storage	275 GB
Instances	7
Security groups	3

Resource	Value
Security group rules	60

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the **swiftoperator** role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

NOTE

By default, your security group and security group rule quotas might be low. If you encounter problems, run **openstack quota set --secgroups 3 --secgroup-rules 60 <project>** as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

15.7.3.1. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

Additionally, for clusters that use single-root input/output virtualization (SR-IOV), RHOSP compute nodes require a flavor that supports [huge pages](#).

IMPORTANT

SR-IOV deployments often employ performance optimizations, such as dedicated or isolated CPUs. For maximum performance, configure your underlying RHOSP deployment to use these optimizations, and then run OpenShift Container Platform compute machines on the optimized infrastructure.

Additional resources

- For more information about configuring performant RHOSP compute nodes, see [Configuring Compute nodes for performance](#).

15.7.3.2. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

15.7.4. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules' repositories and then download them.

NOTE

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

Prerequisites

- Python 3 is installed on your machine.

Procedure

1. On a command line, add the repositories:

- a. Register with Red Hat Subscription Manager:

```
$ sudo subscription-manager register # If not done already
```

- b. Pull the latest subscription data:

```
$ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
```

- c. Disable the current repositories:

```
$ sudo subscription-manager repos --disable=* # If not done already
```

- d. Add the required repositories:

```
$ sudo subscription-manager repos \
--enable=rhel-8-for-x86_64-baseos-rpms \
--enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
```

```
--enable=ansible-2.9-for-rhel-8-x86_64-rpms \
--enable=rhel-8-for-x86_64-appstream-rpms
```

2. Install the modules:

```
$ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr
```

3. Ensure that the **python** command points to **python3**:

```
$ sudo alternatives --set python /usr/bin/python3
```

15.7.5. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

Prerequisites

- The curl command-line tool is available on your machine.

Procedure

- To download the playbooks to your working directory, run the following script from a command line:

```
$ xargs -n 1 curl -O <<< '
https://raw.githubusercontent.com/openshift/installer/release-
4.9/upi/openstack/bootstrap.yaml
https://raw.githubusercontent.com/openshift/installer/release-
4.9/upi/openstack/common.yaml
https://raw.githubusercontent.com/openshift/installer/release-
4.9/upi/openstack/compute-nodes.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/control-
plane.yaml
https://raw.githubusercontent.com/openshift/installer/release-
4.9/upi/openstack/inventory.yaml
https://raw.githubusercontent.com/openshift/installer/release-
4.9/upi/openstack/network.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/security-
groups.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-
bootstrap.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-
compute-nodes.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-
control-plane.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-
load-balancers.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-
network.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-
security-groups.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.9/upi/openstack/down-
containers.yaml'
```

The playbooks are downloaded to your machine.

IMPORTANT

During the installation process, you can modify the playbooks to configure your deployment.

Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.

IMPORTANT

You must match any edits you make in the **bootstrap.yaml**, **compute-nodes.yaml**, **control-plane.yaml**, **network.yaml**, and **security-groups.yaml** files to the corresponding playbooks that are prefixed with **down-**. For example, edits to the **bootstrap.yaml** file must be reflected in the **down-bootstrap.yaml** file, too. If you do not edit both files, the supported cluster removal process will fail.

15.7.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the [Infrastructure Provider](#) page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

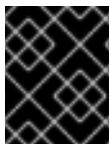

- From the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

15.7.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

Procedure

- If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N " -f <path>/<file_name> ①
```

- Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the **x86_64** architecture, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

- View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> ①
```

- ① Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

15.7.8. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

Prerequisites

- The RHOSP CLI is installed.

Procedure

1. Log in to the Red Hat Customer Portal's [Product Downloads page](#).
2. Under **Version**, select the most recent release of OpenShift Container Platform 4.9 for Red Hat Enterprise Linux (RHEL) 8.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the *Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW)* .
4. Decompress the image.

NOTE

You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like **.gz** or **.tgz**. To find out if or how the file is compressed, in a command line, enter:

```
$ file <name_of_downloaded_file>
```

5. From the image that you downloaded, create an image that is named **rhcose** in your cluster by using the RHOSP CLI:

```
$ openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-  
${RHCOS_VERSION}-openstack.qcow2 rhcos
```

IMPORTANT

Depending on your RHOSP environment, you might be able to upload the image in either [.raw](#) or [.qcow2 formats](#). If you use Ceph, you must use the [.raw](#) format.

WARNING

If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

After you upload the image to RHOSP, it is usable in the installation process.

15.7.9. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Configure OpenStack's networking service to have DHCP agents forward instances' DNS queries

Procedure

- Using the RHOSP CLI, verify the name and ID of the 'External' network:

```
$ openstack network list --long -c ID -c Name -c "Router Type"
```

Example output

ID	Name	Router Type
148a8023-62a7-4672-b018-003462f8d7dc	public_network	External

A network with an external router type appears in the network list. If at least one does not, see [Creating a default floating IP network](#) and [Creating a default provider network](#).

NOTE

If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see [Neutron trunk port](#).

15.7.10. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

15.7.10.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

Procedure

- Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

```
$ openstack floating ip create --description "API <cluster_name>.<base_domain>"<br/><external_network>
```

- Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

```
$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>"<br/><external_network>
```

- By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:

```
$ openstack floating ip create --description "bootstrap machine" <external_network>
```

- Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP><br/>*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

NOTE

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

- Add the FIPs to the **inventory.yaml** file as the values of the following variables:

- os_api_fip**
- os_bootstrap_fip**
- os_ingress_fip**

If you use these values, you must also enter an external network as the value of the **os_external_network** variable in the **inventory.yaml** file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

15.7.10.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the **inventory.yaml** file, do not define the following variables:

- os_api_fip**
- os_bootstrap_fip**
- os_ingress_fip**

If you cannot provide an external network, you can also leave **os_external_network** blank. If you do not provide a value for **os_external_network**, a router is not created for you, and, without additional action,

the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the **wait-for** command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

15.7.11. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called **clouds.yaml**. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the **clouds.yaml** file:

- If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.

IMPORTANT

Remember to add a password to the **auth** field. You can also keep secrets in a separate file from **clouds.yaml**.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about **clouds.yaml**, see [Config files](#) in the RHOSP documentation.

```
clouds:
shiftstack:
auth:
auth_url: http://10.10.14.42:5000/v3
project_name: shiftstack
username: shiftstack_user
password: XXX
user_domain_name: Default
project_domain_name: Default
dev-env:
region_name: RegionOne
auth:
username: 'devuser'
```

```
password: XXX
project_name: 'devonly'
auth_url: 'https://10.10.14.22:5001/v2.0'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
 - a. Copy the certificate authority file to your machine.
 - b. Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

```
clouds:
  shiftstack:
    ...
    cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the **clouds.yaml** file in one of the following locations:
 - a. The value of the **OS_CLIENT_CONFIG_FILE** environment variable
 - b. The current directory
 - c. A Unix-specific user configuration directory, for example **~/.config/openstack/clouds.yaml**
 - d. A Unix-specific site configuration directory, for example **/etc/openstack/clouds.yaml**
The installation program searches for **clouds.yaml** in that order.

15.7.12. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- Have the **imageContentSources** values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.
- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.
- Obtain service principal permissions at the subscription level.

Procedure

1. Create the **install-config.yaml** file.
 - a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir=<installation_directory> ①
```

- 1** For **<installation_directory>**, specify the directory name to store the files that the installation program creates.

IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

- b. At the prompts, provide the configuration details for your cloud:

- i. Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **openstack** as the platform to target.
 - iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.
 - iv. Specify the floating IP address to use for external access to the OpenShift API.
 - v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.
 - vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.
 - vii. Enter a name for your cluster. The name must be 14 or fewer characters long.
 - viii. Paste the pull secret that you obtained from the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site.

2. In the **install-config.yaml** file, set the value of **platform.openstack.clusterOSImage** to the image location or name. For example:

```
platform:
```

```
openstack:
    clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-
openstack.x86_64.qcow2.gz?
sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d
```

3. Edit the **install-config.yaml** file to provide the additional information that is required for an installation in a restricted network.

- a. Update the **pullSecret** value to contain the authentication information for your registry:

```
pullSecret: '{"auths": {"<mirror_host_name>:5000": {"auth": "<credentials>", "email": "you@example.com"}}}'
```

For **<mirror_host_name>**, specify the registry domain name that you specified in the certificate for your mirror registry, and for **<credentials>**, specify the base64-encoded user name and password for your mirror registry.

- b. Add the **additionalTrustBundle** parameter and value.

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

- c. Add the image content resources, which look like this excerpt:

```
imageContentSources:  
- mirrors:  
  - <mirror_host_name>:5000/<repo_name>/release  
    source: quay.example.com/openshift-release-dev/ocp-release  
- mirrors:  
  - <mirror_host_name>:5000/<repo_name>/release  
    source: registry.example.com/ocp/release
```

To complete these values, use the **imageContentSources** that you recorded during mirror registry creation.

4. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.
 5. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file **install-config.yaml** in the directory that you specified.

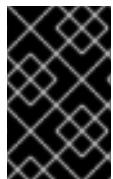

15.7.13. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster's platform. When you create the **install-config.yaml** installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the **install-config.yaml** file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

IMPORTANT

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

15.7.13.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 15.30. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>. <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object

Parameter	Description	Values
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code> .	String of lowercase letters, hyphens (-), and periods (.), such as dev . The string must be 14 characters or fewer long.
platform	The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere , or <code>{}</code> . For additional information about platform . <code><platform></code> parameters, consult the table for your specific platform that follows.	Object
pullSecret	Get a pull secret from https://console.redhat.com/o/penshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths":{ "cloud.openshift.com":{ "auth":"b3Blb=", "email":"you@example.com" }, "quay.io":{ "auth":"b3Blb=", "email":"you@example.com" } } }</pre>

15.7.13.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 15.31. Network parameters

Parameter	Description	Values
-----------	-------------	--------

Parameter	Description	Values
networking	The configuration for the cluster network.	<p>Object</p>  <p>NOTE</p> <p>You cannot modify parameters specified by the networking object after installation.</p>
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	<p>The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23. If you specify multiple IP address blocks, the blocks must not overlap.</p>	<p>An array of objects. For example:</p> <pre>networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</pre>
networking.clusterNetwork.cidr	<p>Required if you use networking.clusterNetwork. An IP address block. An IPv4 network.</p>	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{(32 - 23)} - 2$) pod IP addresses.	<p>A subnet prefix. The default value is 23.</p>
networking.serviceNetwork	<p>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</p>	<p>An array with an IP address block in CIDR format. For example:</p> <pre>networking: serviceNetwork: - 172.30.0.0/16</pre>
networking.machineNetwork	The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.	<p>An array of objects. For example:</p> <pre>networking: machineNetwork: - cidr: 10.0.0.0/16</pre>

Parameter	Description	Values
networking.machineNetwork.cidr	Required if you use networking.machineNetwork . An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24 .	<p>An IP network block in CIDR notation. For example, 10.0.0.0/16.</p>  <p>NOTE Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.</p>

15.7.13.3. Optional configuration parameters

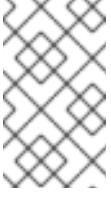

Optional installation configuration parameters are described in the following table:

Table 15.32. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String

Parameter	Description	Values
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	 IMPORTANT <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws , azure , gcp , openstack , ovirt , vsphere , or <code>{}</code>
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String

Parameter	Description	Values
controlPlane.hypert hreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	 IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	<p>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</p>  <p>NOTE</p> <p>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the <i>Cloud Credential Operator</i> entry in the <i>Red Hat Operators</i> reference content.</p>	Mint, Passthrough, Manual , or an empty string ("").
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	false or true

Parameter	Description	Values
imageContentSources	Sources and repositories for the release-image content.	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.	Internal or External . The default value is External . Setting this field to Internal is not supported on non-cloud platforms.
sshKey	The SSH key or keys to authenticate access your cluster machines.  NOTE For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.	One or more keys. For example: sshKey: <key1> <key2> <key3>

15.7.13.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

Table 15.33. Additional RHOSP parameters

Parameter	Description	Values
compute.platform.openstack.rootVolume.size	For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.	Integer, for example 30 .

Parameter	Description	Values
compute.platform.openstack.rootVolume.type	For compute machines, the root volume's type.	String, for example performance .
controlPlane.platform.openstack.rootVolume.size	For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.	Integer, for example 30 .
controlPlane.platform.openstack.rootVolume.type	For control plane machines, the root volume's type.	String, for example performance .
platform.openstack.cloud	The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file.	String, for example MyCloud .
platform.openstack.externalNetwork	The RHOSP external network name to be used for installation.	String, for example external .
platform.openstack.computeFlavor	The RHOSP flavor to use for control plane and compute machines. This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.	String, for example m1.xlarge .

15.7.13.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

Table 15.34. Optional RHOSP parameters

Parameter	Description	Values
compute.platform.openstack.additionalNetworkIDs	Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.	A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .
compute.platform.openstack.additionalSecurityGroupIDs	Additional security groups that are associated with compute machines.	A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7 .
compute.platform.openstack.zones	RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.	A list of strings. For example, ["zone-1", "zone-2"] .
compute.platform.openstack.rootVolume.zones	For compute machines, the availability zone to install root volumes on. If you do not set a value for this parameter, the installer selects the default availability zone.	A list of strings, for example ["zone-1", "zone-2"] .
controlPlane.platform.openstack.additionalNetworkIDs	Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.	A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .
controlPlane.platform.openstack.additionalSecurityGroupIDs	Additional security groups that are associated with control plane machines.	A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7 .

Parameter	Description	Values
controlPlane.platform.openstack.zones	<p>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured.</p> <p>On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</p>	A list of strings. For example, ["zone-1", "zone-2"] .
controlPlane.platform.openstack.rootVolume.zones	For control plane machines, the availability zone to install root volumes on. If you do not set this value, the installer selects the default availability zone.	A list of strings, for example ["zone-1", "zone-2"] .
platform.openstack.clusterOSImage	<p>The location from which the installer downloads the RHCOS image.</p> <p>You must set this parameter to perform an installation in a restricted network.</p>	<p>An HTTP or HTTPS URL, optionally with an SHA-256 checksum.</p> <p>For example, http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d. The value can also be the name of an existing Glance image, for example my-rhcos.</p>

Parameter	Description	Values
platform.openstack.clusterOSImageProperties	<p>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image.</p> <p>You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi.</p> <p>You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</p>	A list of key-value string pairs. For example, <code>["hw_scsi_model": "virtio-scsi", "hw_disk_bus": "scsi"]</code> .
platform.openstack.defaultMachinePlatform	The default machine pool platform configuration.	<pre>{ "type": "ml.large", "rootVolume": { "size": 30, "type": "performance" } }</pre>
platform.openstack.ingressFloatingIP	An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.	An IP address, for example 128.0.0.1 .
platform.openstack.apiFloatingIP	An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property.	An IP address, for example 128.0.0.1 .
platform.openstack.externalDNS	IP addresses for external DNS servers that cluster instances use for DNS resolution.	A list of IP addresses as strings. For example, <code>["8.8.8", "192.168.1.12"]</code> .

Parameter	Description	Values
platform.openstack.machinesSubnet	<p>The UUID of a RHOSP subnet that the cluster's nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.</p> <p>The first item in networking.machineNetwork must match the value of machinesSubnet.</p> <p>If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.</p>	A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .

15.7.13.6. Sample customized `install-config.yaml` file for RHOSP

This sample **install-config.yaml** demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

IMPORTANT

This sample file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program.

```

apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
- name: worker
  platform:
    openstack:
      type: ml.large
  replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
  - cidr: 10.0.0.0/16
  serviceNetwork:
  - 172.30.0.0/16
  networkType: OpenShiftSDN

```

```

platform:
  openstack:
    cloud: mycloud
    externalNetwork: external
    computeFlavor: m1.xlarge
    apiFloatingIP: 128.0.0.1
  fips: false
  pullSecret: '{"auths": ...}'
  sshKey: ssh-ed25519 AAAA...

```

15.7.13.7. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet's GUID is passed as the value of **platform.openstack.machinesSubnet** in the **install-config.yaml** file.

This subnet is used as the cluster's primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the **platform.openstack.machinesSubnet** property to the subnet's UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by **platform.openstack.machinesSubnet** has DHCP enabled.
- The CIDR of **platform.openstack.machinesSubnet** matches the CIDR of **networking.machineNetwork**.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the **platform.openstack.machinesSubnet** subnet must be attached to a router that is connected to the **externalNetwork** network.
- If the **platform.openstack.machinesSubnet** value is set in the **install-config.yaml** file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the **platform.openstack.externalDNS** property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

NOTE

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network's CIDR block. To override these default values, set values for **platform.openstack.apiVIP** and **platform.openstack.ingressVIP** that are outside of the DHCP allocation pool.

15.7.13.8. Setting a custom subnet for machines

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.

Prerequisites

- You have the **install-config.yaml** file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains **install-config.yaml**.
2. From that directory, either run a script to edit the **install-config.yaml** file or update the file manually:
 - To set the value by using a script, run:

```
$ python -c '
import yaml;
path = "install-config.yaml";
data = yaml.safe_load(open(path));
data["networking"]["machineNetwork"] = [{"cidr": "192.168.0.0/18"}]; ①
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

① Insert a value that matches your intended Neutron subnet, e.g. **192.0.2.0/24**.

- To set the value manually, open the file and set the value of **networking.machineCIDR** to something that matches your intended Neutron subnet.

15.7.13.9. Emptying compute machine pools

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

Prerequisites

- You have the **install-config.yaml** file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains **install-config.yaml**.
2. From that directory, either run a script to edit the **install-config.yaml** file or update the file manually:
 - To set the value by using a script, run:

```
$ python -c '
import yaml;
path = "install-config.yaml";
data = yaml.safe_load(open(path));
data["compute"][0]["replicas"] = 0;
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

- To set the value manually, open the file and set the value of **compute.<first entry>.replicas** to **0**.

15.7.14. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the **install-config.yaml** installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir=<installation_directory> ①
```

Example output

```
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift
```

- 1 For **<installation_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

```
$ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

3. Check that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
 - a. Open the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file.
 - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
 - c. Save and exit the file.
4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory> ①
```

- ① For **<installation_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation_directory>/auth** directory:

5. Export the metadata file's **infraID** key as an environment variable:

```
$ export INFRA_ID=$(jq -r .infraID metadata.json)
```

TIP

Extract the **infraID** key from **metadata.json** and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

15.7.15. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

Prerequisites

- You have the bootstrap Ignition file that the installer program generates, **bootstrap.ign**.

- The infrastructure ID from the installer’s metadata file is set as an environment variable (`$INFRA_ID`).
 - If the variable is not set, see [Creating the Kubernetes manifest and Ignition config files](#)
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
 - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

Procedure

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the hostname and, if available, CA certificate file when it runs:

```

import base64
import json
import os

with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

    files = ignition['storage'].get('files', [])

    infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
    hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap\n').decode().strip()
    files.append(
    {
        'path': '/etc/hostname',
        'mode': 420,
        'contents': {
            'source': 'data:text/plain;charset=utf-8;base64,' + hostname_b64
        }
    })
}

ca_cert_path = os.environ.get('OS_CACERT', "")
if ca_cert_path:
    with open(ca_cert_path, 'r') as f:
        ca_cert = f.read().encode()
        ca_cert_b64 = base64.standard_b64encode(ca_cert).decode().strip()

    files.append(
    {
        'path': '/opt/openshift/tls/cloud-ca-cert.pem',
        'mode': 420,
        'contents': {
            'source': 'data:text/plain;charset=utf-8;base64,' + ca_cert_b64
        }
    })
}

ignition['storage']['files'] = files;

with open('bootstrap.ign', 'w') as f:
    json.dump(ignition, f)

```

- Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

```
$ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign <image_name>
```

- Get the image's details:

```
$ openstack image show <image_name>
```

Make a note of the **file** value; it follows the pattern **v2/images/<image_ID>/file**.

NOTE

Verify that the image you created is active.

- Retrieve the image service's public address:

```
$ openstack catalog show image
```

- Combine the public address with the image **file** value and save the result as the storage location. The location follows the pattern **<image_service_public_URL>/v2/images/<image_ID>/file**.

- Generate an auth token and save the token ID:

```
$ openstack token issue -c id -f value
```

- Insert the following content into a file called **\$INFRA_ID-bootstrap-ignition.json** and edit the placeholders to match your own values:

```
{
  "ignition": {
    "config": {
      "merge": [
        {
          "source": "<storage_url>", ①
          "httpHeaders": [
            {
              "name": "X-Auth-Token", ②
              "value": "<token_ID>" ③
            }
          ]
        },
        {
          "security": {
            "tls": {
              "certificateAuthorities": [
                "source": "data:text/plain;charset=utf-8;base64,<base64_encoded_certificate>" ④
              ]
            }
          }
        },
        {
          "version": "3.2.0"
        }
      ]
    }
  }
}
```

- 1 Replace the value of **ignition.config.merge.source** with the bootstrap Ignition file storage URL.
- 2 Set **name** in **httpHeaders** to "X-Auth-Token".
- 3 Set **value** in **httpHeaders** to your token's ID.
- 4 If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.

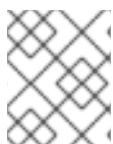

WARNING

The bootstrap Ignition file contains sensitive information, like **clouds.yaml** credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

15.7.16. Creating control plane Ignition config files on RHOSP

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.

NOTE

As with the bootstrap Ignition configuration, you must explicitly define a hostname for each control plane machine.

Prerequisites

- The infrastructure ID from the installation program's metadata file is set as an environment variable (**\$INFRA_ID**).
 - If the variable is not set, see "Creating the Kubernetes manifest and Ignition config files".

Procedure

- On a command line, run the following Python script:

```
$ for index in $(seq 0 2); do
    MASTER_HOSTNAME="$INFRA_ID-master-$index\n"
    python -c "import base64, json, sys;
    ignition = json.load(sys.stdin);
    storage = ignition.get('storage', {});
    files = storage.get('files', []);
    files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {'source':
    'data:text/plain;charset=utf-8;base64,' +
    base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(), 'verification': {}}};"
```

```
'filesystem': 'root'});
storage['files'] = files;
ignition['storage'] = storage
json.dump(ignition, sys.stdout)" <master.ign >"$INFRA_ID-master-$index-ignition.json"
done
```

You now have three control plane Ignition files: **<INFRA_ID>-master-0-ignition.json**, **<INFRA_ID>-master-1-ignition.json**, and **<INFRA_ID>-master-2-ignition.json**.

15.7.17. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.

Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

Procedure

1. Optional: Add an external network value to the **inventory.yaml** playbook:

Example external network value in the **inventory.yaml** Ansible playbook

```
...
# The public network providing connectivity to the cluster. If not
# provided, the cluster external connectivity must be provided in another
# way.

# Required for os_api_fip, os_ingress_fip, os_bootstrap_fip.
os_external_network: 'external'
...
```

IMPORTANT

If you did not provide a value for **os_external_network** in the **inventory.yaml** file, you must ensure that VMs can access Glance and an external connection yourself.

2. Optional: Add external network and floating IP (FIP) address values to the **inventory.yaml** playbook:

Example FIP values in the **inventory.yaml** Ansible playbook

```
...
# OpenShift API floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the Control Plane to
# serve the OpenShift API.
os_api_fip: '203.0.113.23'
```

```

# OpenShift Ingress floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the worker nodes to serve
# the applications.
os_ingress_fip: '203.0.113.19'

# If this value is non-empty, the corresponding floating IP will be
# attached to the bootstrap machine. This is needed for collecting logs
# in case of install failure.
os_bootstrap_fip: '203.0.113.20'

```

IMPORTANT

If you do not define values for **os_api_fip** and **os_ingress_fip**, you must perform post-installation network configuration.

If you do not define a value for **os_bootstrap_fip**, the installer cannot download debugging information from failed installations.

See "Enabling access to the environment" for more information.

3. On a command line, create security groups by running the **security-groups.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml security-groups.yaml
```

4. On a command line, create a network, subnet, and router by running the **network.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml network.yaml
```

5. Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:

```
$ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2>
"--INFRA_ID-nodes"
```

Optionally, you can use the **inventory.yaml** file that you created to customize your installation. For example, you can deploy a cluster that uses bare metal machines.

15.7.17.1. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the **inventory.yaml** file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

NOTE

Be sure that your **install-config.yaml** file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

Prerequisites

- The RHOSP Bare Metal service (Ironic) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a RHOSP flavor.
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
- You created an **inventory.yaml** file as part of the OpenShift Container Platform installation process.

Procedure

1. In the **inventory.yaml** file, edit the flavors for machines:
 - a. If you want to use bare-metal control plane machines, change the value of **os_flavor_master** to a bare metal flavor.
 - b. Change the value of **os_flavor_worker** to a bare metal flavor.

An example bare metal **inventory.yaml** file

```
all:
  hosts:
    localhost:
      ansible_connection: local
      ansible_python_interpreter: "{{ansible_playbook_python}}"

      # User-provided values
      os_subnet_range: '10.0.0.0/16'
      os_flavor_master: 'my-bare-metal-flavor' 1
      os_flavor_worker: 'my-bare-metal-flavor' 2
      os_image_rhcos: 'rhcos'
      os_external_network: 'external'
    ...
  
```

- 1 If you want to have bare-metal control plane machines, change this value to a bare metal flavor.
- 2 Change this value to a bare metal flavor to use for compute machines.

Use the updated **inventory.yaml** file to complete the installation process. Machines that are created during deployment use the flavor that you added to the file.

**NOTE**

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
./openshift-install wait-for install-complete --log-level debug
```

15.7.18. Creating the bootstrap machine on RHOSP

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **bootstrap.yaml** Ansible playbooks are in a common directory.
- The **metadata.json** file that the installation program created is in the same directory as the Ansible playbooks.

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the **bootstrap.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml bootstrap.yaml
```
3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:

```
$ openstack console log show "$INFRA_ID-bootstrap"
```

15.7.19. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The infrastructure ID from the installation program's metadata file is set as an environment variable (**\$INFRA_ID**).
- The **inventory.yaml**, **common.yaml**, and **control-plane.yaml** Ansible playbooks are in a common directory.

- You have the three Ignition files that were created in "Creating control plane Ignition config files".

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. If the control plane Ignition config files aren't already in your working directory, copy them into it.
3. On a command line, run the **control-plane.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml control-plane.yaml
```

4. Run the following command to monitor the bootstrapping process:

```
$ openshift-install wait-for bootstrap-complete
```

You will see messages that confirm that the control plane machines are running and have joined the cluster:

```
INFO API v1.22.1 up  
INFO Waiting up to 30m0s for bootstrapping to complete...  
...  
INFO It is now safe to remove the bootstrap resources
```

15.7.20. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
```

① For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

15.7.21. Deleting bootstrap resources from RHOSP

Delete the bootstrap resources that you no longer need.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **down-bootstrap.yaml** Ansible playbooks are in a common directory.
- The control plane machines are running.
 - If you do not know the status of the machines, see "Verifying cluster status".

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the **down-bootstrap.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml down-bootstrap.yaml
```

The bootstrap port, server, and floating IP address are deleted.

WARNING

If you did not disable the bootstrap Ignition file URL earlier, do so now.

15.7.22. Creating SR-IOV networks for compute machines

If your Red Hat OpenStack Platform (RHOSP) deployment supports [single root I/O virtualization \(SR-IOV\)](#), you can provision SR-IOV networks that compute machines run on.

NOTE

The following instructions entail creating an external flat network and an external, VLAN-based network that can be attached to a compute machine. Depending on your RHOSP deployment, other network types might be required.

Prerequisites

- Your cluster supports SR-IOV.

**NOTE**

If you are unsure about what your cluster supports, review the OpenShift Container Platform SR-IOV hardware networks documentation.

- You created radio and uplink provider networks as part of your RHOSP deployment. The names **radio** and **uplink** are used in all example commands to represent these networks.

Procedure

1. On a command line, create a radio RHOSP network:

```
$ openstack network create radio --provider-physical-network radio --provider-network-type flat --external
```

2. Create an uplink RHOSP network:

```
$ openstack network create uplink --provider-physical-network uplink --provider-network-type vlan --external
```

3. Create a subnet for the radio network:

```
$ openstack subnet create --network radio --subnet-range <radio_network_subnet_range> radio
```

4. Create a subnet for the uplink network:

```
$ openstack subnet create --network uplink --subnet-range <uplink_network_subnet_range> uplink
```

15.7.23. Creating compute machines that run on SR-IOV networks

After standing up the control plane, create compute machines that run on the SR-IOV networks that you created in "Creating SR-IOV networks for compute machines".

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **metadata.yaml** file that the installation program created is in the same directory as the Ansible playbooks.
- The control plane is active.
- You created **radio** and **uplink** SR-IOV networks as described in "Creating SR-IOV networks for compute machines".

Procedure

1. On a command line, change the working directory to the location of the **inventory.yaml** and **common.yaml** files.

2. Add the **radio** and **uplink** networks to the end of the **inventory.yaml** file by using the **additionalNetworks** parameter:

```
....  
# If this value is non-empty, the corresponding floating IP will be  
# attached to the bootstrap machine. This is needed for collecting logs  
# in case of install failure.  
os_bootstrap_fip: '203.0.113.20'  
  
additionalNetworks:  
- id: radio  
  count: 4 1  
  type: direct  
  port_security_enabled: no  
- id: uplink  
  count: 4 2  
  type: direct  
  port_security_enabled: no
```

1 **2** The **count** parameter defines the number of SR-IOV virtual functions (VFs) to attach to each worker node. In this case, each network has four VFs.

3. Replace the content of the **compute-nodes.yaml** file with the following text:

Example 15.1. **compute-nodes.yaml**

```
- import_playbook: common.yaml  
  
- hosts: all  
gather_facts: no  
  
vars:  
  worker_list: []  
  port_name_list: []  
  nic_list: []  
  
tasks:  
# Create the SDN/primary port for each worker node  
- name: 'Create the Compute ports'  
  os_port:  
    name: "{{ item.1 }}-{{ item.0 }}"  
    network: "{{ os_network }}"  
    security_groups:  
      - "{{ os_sg_worker }}"  
    allowed_address_pairs:  
      - ip_address: "{{ os_ingressVIP }}"  
    with_indexed_items: "{{ [os_port_worker] * os_compute_nodes_number }}"  
    register: ports  
  
# Tag each SDN/primary port with cluster name  
- name: 'Set Compute ports tag'  
  command:  
    cmd: "openstack port set --tag {{ cluster_id_tag }} {{ item.1 }}-{{ item.0 }}"  
    with_indexed_items: "{{ [os_port_worker] * os_compute_nodes_number }}"
```

```

- name: 'List the Compute Trunks'
  command:
    cmd: "openstack network trunk list"
    when: os_networking_type == "Kuryr"
    register: compute_trunks

- name: 'Create the Compute trunks'
  command:
    cmd: "openstack network trunk create --parent-port {{ item.1.id }} {{ os_compute_trunk_name }}-{{ item.0 }}"
    with_indexed_items: "{{ ports.results }}"
    when:
      - os_networking_type == "Kuryr"
      - "os_compute_trunk_name|string not in compute_trunks.stdout"

- name: 'Call additional-port processing'
  include_tasks: additional-ports.yaml

# Create additional ports in OpenStack
- name: 'Create additionalNetworks ports'
  os_port:
    name: "{{ item.0 }}-{{ item.1.name }}"
    vnic_type: "{{ item.1.type }}"
    network: "{{ item.1.uuid }}"
    port_security_enabled: "{{ item.1.port_security_enabled|default(omit) }}"
    no_security_groups: "{{ 'true' if item.1.security_groups is not defined else omit }}"
    security_groups: "{{ item.1.security_groups | default(omit) }}"
  with_nested:
    - "{{ worker_list }}"
    - "{{ port_name_list }}"

# Tag the ports with the cluster info
- name: 'Set additionalNetworks ports tag'
  command:
    cmd: "openstack port set --tag {{ cluster_id_tag }} {{ item.0 }}-{{ item.1.name }}"
  with_nested:
    - "{{ worker_list }}"
    - "{{ port_name_list }}"

# Build the nic list to use for server create
- name: Build nic list
  set_fact:
    nic_list: "{{ nic_list | default([]) + [ item.name ] }}"
  with_items: "{{ port_name_list }}"

# Create the servers
- name: 'Create the Compute servers'
  vars:
    worker_nics: "{{ [ item.1 ] | product(nic_list) | map('join','-) | map('regex_replace', '(.*)', 'port-name=\1') | list }}"
  os_server:
    name: "{{ item.1 }}"
    image: "{{ os_image_rhcos }}"
    flavor: "{{ os_flavor_worker }}"
    auto_ip: no
    userdata: "{{ lookup('file', 'worker.ign') | string }}"

```

```

    security_groups: []
    nics: "{{ [ 'port-name=' + os_port_worker + '-' + item.0|string ] + worker_nics }}"
    config_drive: yes
    with_indexed_items: "{{ worker_list }}"

```

4. Insert the following content into a local file that is called **additional-ports.yaml**:

Example 15.2. additional-ports.yaml

```

# Build a list of worker nodes with indexes
- name: 'Build worker list'
  set_fact:
    worker_list: "{{ worker_list | default([]) + [ item.1 + '-' + item.0 | string ] }}"
    with_indexed_items: "{{ [ os_compute_server_name ] * os_compute_nodes_number }}"

# Ensure that each network specified in additionalNetworks exists
- name: 'Verify additionalNetworks'
  os_networks_info:
    name: "{{ item.id }}"
  with_items: "{{ additionalNetworks }}"
  register: network_info

# Expand additionalNetworks by the count parameter in each network definition
- name: 'Build port and port index list for additionalNetworks'
  set_fact:
    port_list: "{{ port_list | default([]) + [ {
      'net_name' : item.1.id,
      'uuid' : network_info.results[item.0].openstack_networks[0].id,
      'type' : item.1.type|default('normal'),
      'security_groups' : item.1.security_groups|default(omit),
      'port_security_enabled' : item.1.port_security_enabled|default(omit)
    } ] * item.1.count|default(1) }}"
    index_list: "{{ index_list | default([]) + range(item.1.count|default(1)) | list }}"
    with_indexed_items: "{{ additionalNetworks }}"

# Calculate and save the name of the port
# The format of the name is cluster_name-worker-workerID-networkUUID(partial)-count
# i.e. fdp-nz995-worker-1-99bcd111-1
- name: 'Calculate port name'
  set_fact:
    port_name_list: "{{ port_name_list | default([]) + [ item.1 | combine( {'name' : item.1.uuid
      | regex_search('(^-+)' + '-' + index_list[item.0]|string ) } ) ] }}"
    with_indexed_items: "{{ port_list }}"
    when: port_list is defined

```

5. On a command line, run the **compute-nodes.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml compute-nodes.yaml
```

15.7.24. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 63m v1.22.1
master-1 Ready master 63m v1.22.1
master-2 Ready master 64m v1.22.1
```

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

```
NAME AGE REQUESTOR CONDITION
csr-8b2br 15m system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending
csr-8vnps 15m system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending
...
...
```

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approvers** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

NOTE

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	Pending
csr-c57lv	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	Pending
	...		

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}\n{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	73m	v1.22.1
master-1	Ready	master	73m	v1.22.1
master-2	Ready	master	74m	v1.22.1
worker-0	Ready	worker	11m	v1.22.1
worker-1	Ready	worker	11m	v1.22.1

NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

15.7.25. Verifying a successful installation

Verify that the OpenShift Container Platform installation is complete.

Prerequisites

- You have the installation program (**openshift-install**)

Procedure

- On a command line, enter:

```
$ openshift-install --log-level debug wait-for install-complete
```

The program outputs the console URL, as well as the administrator's login information.

The cluster is operational. Before you can configure it for SR-IOV networks though, you must perform additional tasks.

15.7.26. Preparing a cluster that runs on RHOSP for SR-IOV

Before you use [single root I/O virtualization \(SR-IOV\)](#) on a cluster that runs on Red Hat OpenStack Platform (RHOSP), make the RHOSP metadata service mountable as a drive and enable the No-IOMMU Operator for the virtual function I/O (VFIO) driver.

15.7.26.1. Enabling the RHOSP metadata service as a mountable drive

You can apply a machine config to your machine pool that makes the Red Hat OpenStack Platform (RHOSP) metadata service available as a mountable drive.

The following machine config enables the display of RHOSP network UUIDs from within the SR-IOV Network Operator. This configuration simplifies the association of SR-IOV resources to cluster SR-IOV resources.

Procedure

1. Create a machine config file from the following template:

A mountable metadata service machine config file

```
kind: MachineConfig
apiVersion: machineconfiguration.openshift.io/v1
metadata:
  name: 20-mount-config ①
  labels:
    machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    systemd:
      units:
        - name: create-mountpoint-var-config.service
          enabled: true
          contents: |
            [Unit]
            Description=Create mountpoint /var/config
            Before=kubelet.service

            [Service]
            ExecStart=/bin/mkdir -p /var/config

            [Install]
            WantedBy=var-config.mount

        - name: var-config.mount
          enabled: true
          contents: |
            [Unit]
            Before=local-fs.target
            [Mount]
```

```
Where=/var/config
What=/dev/disk/by-label/config-2
[Install]
WantedBy=local-fs.target
```

- 1 You can substitute a name of your choice.

2. From a command line, apply the machine config:

```
$ oc apply -f <machine_config_file_name>.yaml
```

15.7.26.2. Enabling the No-IOMMU feature for the RHOSP VFIO driver

You can apply a machine config to your machine pool that enables the No-IOMMU feature for the Red Hat OpenStack Platform (RHOSP) virtual function I/O (VFIO) driver. The RHOSP vfio-pci driver requires this feature.

Procedure

1. Create a machine config file from the following template:

A No-IOMMU VFIO machine config file

```
kind: MachineConfig
apiVersion: machineconfiguration.openshift.io/v1
metadata:
  name: 99-vfio-noiommu ①
  labels:
    machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      files:
        - path: /etc/modprobe.d/vfio-noiommu.conf
          mode: 0644
          contents:
            source:
              data::base64,b3B0aW9ucyB2ZmlvIGVuYWJsZV91bnNhZmVfbm9pb21tdV9tb2RIPTEK
```

- 1 You can substitute a name of your choice.

2. From a command line, apply the machine config:

```
$ oc apply -f <machine_config_file_name>.yaml
```

NOTE

After you apply the machine config to the machine pool, you can [watch the machine config pool status](#) to see when the machines are available.

The cluster is installed and prepared for SR-IOV configuration. You must now perform the SR-IOV configuration tasks in "Next steps".

15.7.27. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.9, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager \(OCM\)](#).

After you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OCM, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

15.7.28. Additional resources

- See [Performance Addon Operator for low latency nodes](#) for information about configuring your deployment for real-time running and low latency.

15.7.29. Next steps

- To complete SR-IOV configuration for your cluster:
 - [Install the Performance Addon Operator](#).
 - [Configure the Performance Addon Operator with huge pages support](#).
 - [Install the SR-IOV Operator](#).
 - [Configure your SR-IOV network device](#).
- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- If you need to enable external access to node ports, [configure ingress cluster traffic by using a node port](#).
- If you did not configure RHOSP to accept application traffic over floating IP addresses, [configure RHOSP access with floating IP addresses](#).

15.8. INSTALLING A CLUSTER ON OPENSTACK IN A RESTRICTED NETWORK

In OpenShift Container Platform 4.9, you can install a cluster on Red Hat OpenStack Platform (RHOSP) in a restricted network by creating an internal mirror of the installation release content.

15.8.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You verified that OpenShift Container Platform 4.9 is compatible with your RHOSP version by using the [Supported platforms for OpenShift clusters](#) section. You can also compare platform support across different versions by viewing the [OpenShift Container Platform on RHOSP support matrix](#).
- You [created a registry on your mirror host](#) and obtained the **imageContentSources** data for your version of OpenShift Container Platform.

IMPORTANT

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You have the metadata service enabled in RHOSP.

15.8.2. About installations in restricted networks

In OpenShift Container Platform 4.9, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require internet access, so you might still require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

15.8.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

15.8.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

Table 15.35. Recommended resources for a default OpenShift Container Platform cluster on RHOSP

Resource	Value
Floating IP addresses	3
Ports	15
Routers	1
Subnets	1
RAM	112 GB
vCPUs	28
Volume storage	275 GB
Instances	7
Security groups	3
Security group rules	60

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the **swiftoperator** role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

NOTE

By default, your security group and security group rule quotas might be low. If you encounter problems, run **openstack quota set --secgroups 3 --secgroup-rules 60 <project>** as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

15.8.3.1. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota

- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

15.8.3.2. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

15.8.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.9, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access the [Red Hat OpenShift Cluster Manager](#) page to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

15.8.5. Enabling Swift on RHOSP

Swift is operated by a user account with the **swiftoperator** role. Add the role to an account before you run the installation program.

IMPORTANT

If [the Red Hat OpenStack Platform \(RHOSP\) object storage service](#), commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

Prerequisites

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
- On [Ceph RGW](#), the **account in url** option is enabled.

Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the **swiftoperator** role to the account that will access Swift:

```
$ openstack role add --user <user> --project <project> swiftoperator
```

Your RHOSP deployment can now use Swift for the image registry.

15.8.6. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called **clouds.yaml**. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the **clouds.yaml** file:
 - If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.

IMPORTANT

Remember to add a password to the **auth** field. You can also keep secrets in a [separate file](#) from **clouds.yaml**.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about **clouds.yaml**, see [Config files](#) in the RHOSP documentation.

```
clouds:
  shiftstack:
    auth:
      auth_url: http://10.10.14.42:5000/v3
      project_name: shiftstack
```

```

username: shiftstack_user
password: XXX
user_domain_name: Default
project_domain_name: Default
dev-env:
region_name: RegionOne
auth:
username: 'devuser'
password: XXX
project_name: 'devonly'
auth_url: 'https://10.10.14.22:5001/v2.0'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
 - a. Copy the certificate authority file to your machine.
 - b. Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

```

clouds:
shiftstack:
...
cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the **clouds.yaml** file in one of the following locations:
 - a. The value of the **OS_CLIENT_CONFIG_FILE** environment variable
 - b. The current directory
 - c. A Unix-specific user configuration directory, for example **~/.config/openstack/clouds.yaml**
 - d. A Unix-specific site configuration directory, for example **/etc/openstack/clouds.yaml**
The installation program searches for **clouds.yaml** in that order.

15.8.7. Setting cloud provider options

Optionally, you can edit the cloud provider configuration for your cluster. The cloud provider configuration controls how OpenShift Container Platform interacts with Red Hat OpenStack Platform (RHOSP).

For a complete list of cloud provider configuration parameters, see [the **cloud.conf** specification](#).

Procedure

- If you have not already generated manifest files for your cluster, generate them by running the following command:

```
$ openshift-install --dir <destination_directory> create manifests
```

- In a text editor, open the cloud-provider configuration manifest file. For example:

```
$ vi openshift/manifests/cloud-provider-config.yaml
```

- Modify the options based on [the **cloud.conf** specification](#).

Configuring Octavia for load balancing is a common case. For example:

```
#...
[LoadBalancer]
use-octavia=true 1
lb-provider = "amphora" 2
floating-network-id="d3deb660-4190-40a3-91f1-37326fe6ec4a" 3
#...
```

- 1** This property enables Octavia integration.
- 2** This property sets the Octavia provider that your load balancer uses. It accepts "**ovn**" or "**amphora**" as values. If you choose to use OVN, you must also set **lb-method** to **SOURCE_IP_PORT**.
- 3** This property is required if you want to use multiple external networks with your cluster. The cloud provider creates floating IP addresses on the network that is specified here.

IMPORTANT

Prior to saving your changes, verify that the file is structured correctly. Clusters might fail if properties are not placed in the appropriate section.

- Save the changes to the file and proceed with installation.

TIP

You can update your cloud provider configuration after you run the installer. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

After you save your changes, your cluster will take some time to reconfigure itself. The process is complete if none of your nodes have a **SchedulingDisabled** status.

15.8.8. Creating the RHCOS image for restricted network installations

Download the Red Hat Enterprise Linux CoreOS (RHCOS) image to install OpenShift Container Platform on a restricted network Red Hat OpenStack Platform (RHOSP) environment.

Prerequisites

- Obtain the OpenShift Container Platform installation program. For a restricted network installation, the program is on your mirror registry host.

Procedure

1. Log in to the Red Hat Customer Portal's [Product Downloads page](#).
2. Under **Version**, select the most recent release of OpenShift Container Platform 4.9 for RHEL 8.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the **Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW)** image.
4. Decompress the image.

NOTE

You must decompress the image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like **.gz** or **.tgz**. To find out if or how the file is compressed, in a command line, enter:

```
$ file <name_of_downloaded_file>
```

5. Upload the image that you decompressed to a location that is accessible from the bastion server, like Glance. For example:

```
$ openstack image create --file rhcos-44.81.202003110027-0-openstack.x86_64.qcow2 --disk-format qcow2 rhcos-${RHCOS_VERSION}
```

IMPORTANT

Depending on your RHOSP environment, you might be able to upload the image in either **.raw** or **.qcow2** formats. If you use Ceph, you must use the **.raw** format.

WARNING

If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

The image is now available for a restricted installation. Note the image name or location for use in OpenShift Container Platform deployment.

15.8.9. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- Have the **imageContentSources** values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.
- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.
- Obtain service principal permissions at the subscription level.

Procedure

1. Create the **install-config.yaml** file.
 - a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir=<installation_directory> ①
```
 - 1 For **<installation_directory>**, specify the directory name to store the files that the installation program creates.

IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

- b. At the prompts, provide the configuration details for your cloud:
 - i. Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **openstack** as the platform to target.
 - iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.
 - iv. Specify the floating IP address to use for external access to the OpenShift API.
 - v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.
 - vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.
 - vii. Enter a name for your cluster. The name must be 14 or fewer characters long.
 - viii. Paste the pull secret that you obtained from the [Pull Secret](#) page on the Red Hat OpenShift Cluster Manager site.
2. In the **install-config.yaml** file, set the value of **platform.openstack.clusterOSImage** to the image location or name. For example:

```
platform:
  openstack:
    clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-
    openstack.x86_64.qcow2.gz?
    sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265
```

3. Edit the **install-config.yaml** file to provide the additional information that is required for an installation in a restricted network.

- a. Update the **pullSecret** value to contain the authentication information for your registry:

```
pullSecret: '{"auths": {"<mirror_host_name>:5000": {"auth": "<credentials>","email": "you@example.com"}}}
```

For **<mirror_host_name>**, specify the registry domain name that you specified in the certificate for your mirror registry, and for **<credentials>**, specify the base64-encoded user name and password for your mirror registry.

- b. Add the **additionalTrustBundle** parameter and value.

```
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
  -----END CERTIFICATE-----
```

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

- c. Add the image content resources, which look like this excerpt:

```
imageContentSources:
- mirrors:
  - <mirror_host_name>:5000/<repo_name>/release
```

```

source: quay.example.com/openshift-release-dev/ocp-release
- mirrors:
  - <mirror_host_name>:5000/<repo_name>/release
source: registry.example.com/ocp/release

```

To complete these values, use the **imageContentSources** that you recorded during mirror registry creation.

4. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.
5. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

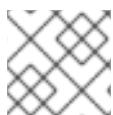

IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

15.8.9.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

NOTE

Kuryr installations default to HTTP proxies.

Prerequisites

- For Kuryr installations on restricted networks that use the **Proxy** object, the proxy must be able to reply to the router that the cluster uses. To add a static route for the proxy configuration, from a command line as the root user, enter:

```
$ ip route add <cluster_network_cidr> via <installer_subnet_gateway>
```
- The restricted subnet must have a gateway that is defined and available to be linked to the **Router** resource that Kuryr creates.
- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the **ec2.<region>.amazonaws.com**, **elasticloadbalancing.<region>.amazonaws.com**, and **s3.<region>.amazonaws.com** endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

- Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ①
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
  noProxy: example.com ③
  additionalTrustBundle: | ④
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
...

```

- A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpProxy** value.
- A proxy URL to use for creating HTTPS connections outside the cluster. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an **httpsProxy** value.
- A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use ***** to bypass the proxy for all destinations.
- If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace to hold the additional CA certificates. If you provide **additionalTrustBundle** and at least one proxy setting, the **Proxy** object is configured to reference the **user-ca-bundle** config map in the **trustedCA** field. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges the contents specified for the **trustedCA** parameter with the RHCOS trust bundle. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by

an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE

The installation program does not support the proxy **readinessEndpoints** field.

- Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

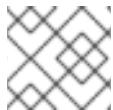

NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

15.8.9.2. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster's platform. When you create the **install-config.yaml** installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the **install-config.yaml** file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

IMPORTANT

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

15.8.9.2.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 15.36. Required parameters

Parameter	Description	Values
apiVersion	The API version for the install-config.yaml content. The current version is v1 . The installer may also support older API versions.	String

Parameter	Description	Values
baseDomain	The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <metadata.name>. <baseDomain> format.	A fully-qualified domain or subdomain name, such as example.com .
metadata	Kubernetes resource ObjectMeta , from which only the name parameter is consumed.	Object
metadata.name	The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}} .	String of lowercase letters, hyphens (-), and periods (.), such as dev . The string must be 14 characters or fewer long.
platform	The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere , or {} . For additional information about platform . <platform> parameters, consult the table for your specific platform that follows.	Object
pullSecret	Get a pull secret from https://console.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.	<pre>{ "auths":{ "cloud.openshift.com":{ "auth":"b3Blb=", "email":"you@example.com" }, "quay.io":{ "auth":"b3Blb=", "email":"you@example.com" } } }</pre>

15.8.9.2.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 15.37. Network parameters

Parameter	Description	Values
networking	The configuration for the cluster network.	<p>Object</p>  <p>NOTE</p> <p>You cannot modify parameters specified by the networking object after installation.</p>
networking.networkType	The cluster network provider Container Network Interface (CNI) plug-in to install.	Either OpenShiftSDN or OVNKubernetes . The default value is OpenShiftSDN .
networking.clusterNetwork	<p>The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>	<p>An array of objects. For example:</p> <pre>networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</pre>
networking.clusterNetwork.cidr	<p>Required if you use networking.clusterNetwork. An IP address block.</p> <p>An IPv4 network.</p>	An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32 .
networking.clusterNetwork.hostPrefix	The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr . A hostPrefix value of 23 provides 510 ($2^{(32 - 23)} - 2$) pod IP addresses.	<p>A subnet prefix.</p> <p>The default value is 23.</p>

Parameter	Description	Values
networking.serviceNetwork	<p>The IP address block for services. The default value is 172.30.0.0/16.</p> <p>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</p>	An array with an IP address block in CIDR format. For example:
		<pre>networking: serviceNetwork: - 172.30.0.0/16</pre>
networking.machineNetwork	<p>The IP address blocks for machines.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>	An array of objects. For example:
		<pre>networking: machineNetwork: - cidr: 10.0.0.0/16</pre>
networking.machineNetwork.cidr	<p>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</p>	<p>An IP network block in CIDR notation.</p> <p>For example, 10.0.0.0/16.</p>  <p>NOTE</p> <p>Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.</p>

15.8.9.2.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 15.38. Optional parameters

Parameter	Description	Values
additionalTrustBundle	A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.	String
compute	The configuration for the machines that comprise the compute nodes.	Array of MachinePool objects.

Parameter	Description	Values
compute.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String
compute.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	 IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.	
compute.name	Required if you use compute . The name of the machine pool.	worker
compute.platform	Required if you use compute . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere , or {}
compute.replicas	The number of compute machines, which are also known as worker machines, to provision.	A positive integer greater than or equal to 2 . The default value is 3 .
controlPlane	The configuration for the machines that comprise the control plane.	Array of MachinePool objects.

Parameter	Description	Values
controlPlane.architecture	Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).	String
controlPlane.hyperthreading	Whether to enable or disable simultaneous multithreading, or hyperthreading , on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.	Enabled or Disabled
	<p> IMPORTANT</p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p>	
controlPlane.name	Required if you use controlPlane . The name of the machine pool.	master
controlPlane.platform	Required if you use controlPlane . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.	aws, azure, gcp, openstack, ovirt, vsphere, or {}
controlPlane.replicas	The number of control plane machines to provision.	The only supported value is 3 , which is the default value.

Parameter	Description	Values
credentialsMode	<p>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</p>  <p>NOTE</p> <p>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the <i>Cloud Credential Operator</i> entry in the <i>Red Hat Operators</i> reference content.</p>	Mint, Passthrough, Manual , or an empty string ("").
tips	<p>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p>  <p>IMPORTANT</p> <p>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</p>  <p>NOTE</p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p>	false or true

Parameter	Description	Values
imageContentSources	Sources and repositories for the release-image content.	Array of objects. Includes a source and, optionally, mirrors , as described in the following rows of this table.
imageContentSources.source	Required if you use imageContentSources . Specify the repository that users refer to, for example, in image pull specifications.	String
imageContentSources.mirrors	Specify one or more repositories that may also contain the same images.	Array of strings
publish	How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.	Internal or External . The default value is External . Setting this field to Internal is not supported on non-cloud platforms.
sshKey	The SSH key or keys to authenticate access your cluster machines. 	One or more keys. For example: sshKey: <key1> <key2> <key3>

15.8.9.2.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

Table 15.39. Additional RHOSP parameters

Parameter	Description	Values
compute.platform.openstack.rootVolume.size	For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.	Integer, for example 30 .

Parameter	Description	Values
compute.platform.openstack.rootVolume.type	For compute machines, the root volume's type.	String, for example performance .
controlPlane.platform.openstack.rootVolume.size	For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.	Integer, for example 30 .
controlPlane.platform.openstack.rootVolume.type	For control plane machines, the root volume's type.	String, for example performance .
platform.openstack.cloud	The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file.	String, for example MyCloud .
platform.openstack.externalNetwork	The RHOSP external network name to be used for installation.	String, for example external .
platform.openstack.computeFlavor	The RHOSP flavor to use for control plane and compute machines. This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.	String, for example m1.xlarge .

15.8.9.2.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

Table 15.40. Optional RHOSP parameters

Parameter	Description	Values
compute.platform.openstack.additionalNetworkIDs	Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.	A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .
compute.platform.openstack.additionalSecurityGroupIDs	Additional security groups that are associated with compute machines.	A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7 .
compute.platform.openstack.zones	<p>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured.</p> <p>On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</p>	A list of strings. For example, ["zone-1", "zone-2"] .
compute.platform.openstack.rootVolume.zones	For compute machines, the availability zone to install root volumes on. If you do not set a value for this parameter, the installer selects the default availability zone.	A list of strings, for example ["zone-1", "zone-2"] .
controlPlane.platform.openstack.additionalNetworkIDs	Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.	A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .
controlPlane.platform.openstack.additionalSecurityGroupIDs	Additional security groups that are associated with control plane machines.	A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7 .

Parameter	Description	Values
controlPlane.platform.openstack.zones	RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.	A list of strings. For example, ["zone-1", "zone-2"] .
controlPlane.platform.openstack.rootVolume.zones	For control plane machines, the availability zone to install root volumes on. If you do not set this value, the installer selects the default availability zone.	A list of strings, for example ["zone-1", "zone-2"] .
platform.openstack.clusterOSImage	The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.	An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d . The value can also be the name of an existing Glance image, for example my-rhcos .

Parameter	Description	Values
platform.openstack.clusterOSImageProperties	<p>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image.</p> <p>You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi.</p> <p>You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</p>	A list of key-value string pairs. For example, <code>["hw_scsi_model": "virtio-scsi", "hw_disk_bus": "scsi"]</code> .
platform.openstack.defaultMachinePlatform	The default machine pool platform configuration.	<pre>{ "type": "ml.large", "rootVolume": { "size": 30, "type": "performance" } }</pre>
platform.openstack.ingressFloatingIP	An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.	An IP address, for example 128.0.0.1 .
platform.openstack.apiFloatingIP	An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property.	An IP address, for example 128.0.0.1 .
platform.openstack.externalDNS	IP addresses for external DNS servers that cluster instances use for DNS resolution.	A list of IP addresses as strings. For example, <code>["8.8.8", "192.168.1.12"]</code> .

Parameter	Description	Values
platform.openstack.machinesSubnet	<p>The UUID of a RHOSP subnet that the cluster's nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.</p> <p>The first item in networking.machineNetwork must match the value of machinesSubnet.</p> <p>If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.</p>	A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf .

15.8.9.3. Sample customized `install-config.yaml` file for restricted OpenStack installations

This sample **install-config.yaml** demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

IMPORTANT

This sample file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program.

```

apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
- name: worker
  platform:
    openstack:
      type: ml.large
    replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineCIDR: 10.0.0.0/16
  serviceNetwork:
  - 172.30.0.0/16
  networkType: OpenShiftSDN
platform:
```

```
openstack
region: region1
cloud: mycloud
externalNetwork: external
computeFlavor: m1.xlarge
apiFloatingIP: 128.0.0.1
fips: false
pullSecret: '{"auths": ...}'
sshKey: ssh-ed25519 AAAA...
additionalTrustBundle: |
```

-----BEGIN CERTIFICATE-----

-----END CERTIFICATE-----

```

  - <mirror_registry>/<repo_name>/release  
    source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
```

15.8.10. Setting compute machine affinity

Optionally, you can set the affinity policy for compute machines during installation. The installer does not select an affinity policy for compute machines by default.

You can also create machine sets that use particular RHOSP server groups after installation.

NOTE

Control plane machines are created with a **soft-anti-affinity** policy.

TIP

You can learn more about [RHOSP instance scheduling and placement](#) in the RHOSP documentation.

Prerequisites

- Create the **install-config.yaml** file and complete any modifications to it.

Procedure

1. Using the RHOSP command-line interface, create a server group for your compute machines.
For example:

```
$ openstack \
    --os-compute-api-version=2.15 \
    server group create \
    --policy anti-affinity \
    my-openshift-worker-group
```

For more information, see the [server group create command documentation](#).

2. Change to the directory that contains the installation program and create the manifests:

```
$ ./openshift-install create manifests --dir=<installation_directory>
```

where:

installation_directory

Specifies the name of the directory that contains the **install-config.yaml** file for your cluster.

3. Open **manifests/99_openshift-cluster-api_worker-machineset-0.yaml**, the **MachineSet** definition file.
4. Add the property **serverGroupID** to the definition beneath the **spec.template.spec.providerSpec.value** property. For example:

```
apiVersion: machine.openshift.io/v1beta1
kind: MachineSet
metadata:
  labels:
    machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
    machine.openshift.io/cluster-api-machine-role: <node_role>
    machine.openshift.io/cluster-api-machine-type: <node_role>
